- 15 vulnerability?
- 16 9.2: What will be the major climate change impacts and adaptations in rural areas across the world?

18 References

21 Executive Summary

23 **Rural areas still account for almost half the world's population, about 75% of the developing world's poor people and 80% of the world's hungry.** [9.1.1] There is a lack of clear definition of what constitutes rural areas, and definitions that do exist depend on definitions of the urban. [9.1.2] Across the world, the importance of peri-urban areas and new forms of rural-urban interactions are increasing. [9.1.3] However, rural areas, seen as a dynamic, spatial category remain important for assessing the impacts of climate change and the prospects of adaptation. [9.1.1] A lack of focus on rural areas in policy making increases their vulnerability to climate change. [9.2]

31 **Climate change in rural areas will take place in the context of many important economic, social and land-use trends** (*very high confidence*). In different regions, rural populations have peaked or will peak in the next few decades. [9.3.1] The proportion of the rural population depending on agriculture is extremely varied across regions, but declining everywhere. Poverty rates in rural areas are falling more sharply than overall poverty rates, and proportions of the total poor accounted for by rural people are also falling: in both cases with the exception of sub-Saharan Africa, where these rates are rising.

38 **Rural people in developing countries are subject to multiple non-climate stressors, including under-investment in agriculture (though there are signs this is improving), problems with land policy, and processes of environmental degradation** (*high to very high confidence*). Hunger and malnutrition remain prevalent among rural children in South Asia and Sub-Saharan Africa. In developing countries, the levels and distribution of rural policies are affected in complex and interacting ways by processes of commercialisation and diversification, food policies, and policies on land tenure. In industrialized countries, there are important shifts towards multiple uses of rural areas, especially leisure uses, and new rural policies based on the collaboration of multiple stakeholders, the targeting of multiple sectors and a change from subsidy-based to investment-based policy. [9.3.1, Table 9-1]

47 **Prevailing development constraints, such as low levels of educational attainment, environmental degradation and gender inequality create additional vulnerabilities to climate change [9.4.4]** (*high confidence*). There are low levels of agreement on some of the key factors associated with vulnerability or resilience in rural areas [9.3.5.2], including rainfed as opposed to irrigated agriculture [9.3.5.2.1], small-scale and family-managed farms [9.3.5.2.2], and integration into world markets. [9.3.5.2.4]. There is greater agreement on the importance for resilience of access to land and natural resources [9.3.5.2.5], flexible local institutions [9.3.5.2.6], and knowledge and information [9.3.5.2.7], and the association of gender inequalities with vulnerability. [9.3.5.2.9]. Specific livelihood niches such as pastoralism, mountain farming systems, and artisanal fisheries are vulnerable and at high risk of adverse impacts

1 (*medium to high confidence*), partly due to neglect, misunderstanding or inappropriate policy towards them on the
2 part of governments.
3

4 **Cases in the literature of observed impacts on rural areas often suffer from methodological problems of**
5 **attribution, but evidence for observed impacts, both of extreme events and other categories, is increasing.**
6 **[9.3.2] (*medium confidence*).** Impacts attributable to climate change include declining yields of major crops, extreme
7 events such as droughts and storms, and geographically-specific impacts such as glacier melt in the Andes.
8

9 **Future impacts of climate change on the rural economic base and livelihoods, land-use and regional**
10 **interconnections are at the latter stages of complex causal chains (*high confidence*).** These flow through
11 changing patterns of extreme events and/or effects of climate change on biophysical processes in agriculture and
12 less-managed ecosystems. This increases the uncertainty associated with any particular projected impact. [9.3.3]
13

14 **Major impacts of climate change in rural areas will be felt through impacts on water supply, food security**
15 **[9.3.3.1] and agricultural incomes. [9.3.4.1] (*high confidence*).** In certain countries shifts in agricultural
16 production, of food and non-food crops, could take place. [9.3.3.1] Price rises, which may be induced by climate
17 shocks apart from other factors [9.3.3.2], have a disproportionate impact on the welfare of the poor in rural areas,
18 such as female headed households and those with limited access to modern agricultural inputs, infrastructure and
19 education. [9.3.3.1]
20

21 **Climate change will lead to higher prices and increased volatility in agricultural markets, which might**
22 **undermine global food supply security while affecting rural households depending on whether they are net-**
23 **buyers or net-sellers of food. [9.3.3.3] (*medium to high confidence*).** There is medium level agreement that
24 deepening agricultural markets through trade reform and institutional efforts to improve the predictability and the
25 reliability of the world trading system as well as by investing in additional supply capacity of small-scale farms in
26 developing countries could help reduce market volatility and manage food supply shortages which might be caused
27 by climate change [9.3.3.2]
28

29 **Migration patterns will be driven by multiple factors of which climate change is only one [9.3.3.1] (*high***
30 ***confidence*).** Given these multiple drivers of migration and the complex interactions which mediate migratory
31 decision-making by individual or households, the detection of the effects of climate change on intra-rural and rural-
32 to-urban migration remains a major challenge.
33

34 **Climate policies, such as encouraging cultivation of biofuels, and payments under REDD, will have significant**
35 **secondary impacts on land-use, and resulting negative impact on livelihoods, in some rural areas. [9.3.3.4]**
36 **(*medium confidence*).** These secondary impacts, and trade-offs between mitigation and adaptation in rural areas,
37 have implications for governance.
38

39 **Most studies on valuation highlight that climate change impacts will be significant especially for the**
40 **developing regions, due to their economic dependence on agriculture and natural resources, low adaptive**
41 **capacities, and geographical locations. [9.3.4] (*high confidence*).** Valuation of climate impacts needs to draw upon
42 both monetary and non-monetary indicators. The valuation of non-marketed ecosystem services [9.3.4.6] and the
43 limitations of economic valuation models which aggregate across multiple contexts [9.3.4] pose challenges for
44 valuing impacts in rural areas.
45

46 **There is a growing body of literature on successful adaptation in rural areas, including documentation of**
47 **practical experience [9.4.3].** Gender, the supply of information for decision-making, and the role of social capital in
48 building resilience, are all key issues. [9.4.1] Constraints to adaptation come from lack of access to credit, land,
49 water, technology, markets and information; and are particularly pronounced in developing countries. [9.4.4] (*high*
50 *confidence*)

53

9.1. Introduction

9.1.1. Rationale for the Chapter

Rural areas, even after significant demographic shifts, still account for 3.3 billion people or almost half (47.9%) of the world's total population (UN-DESA Population Division 2012). The proportion of people in developing countries living in rural areas is higher than the global average, with 71.5% of the population (or about 608 million people) living in rural areas in the least developed countries, and 50.3% of the population (or about 2.5 billion people) living in rural areas in other less developed countries (excluding LDCs), – compared to only 22.3% of the population (or about 276 million people) in more developed countries.

The overwhelming majority of the world's rural population (3.1 billion people, or 91.7% of the world's rural population, or 44.0% of the world's total population) live in rural areas in less developed or least developed countries. Rural dwellers also account for about 75% of the developing world's poor people (Ravaillon *et al.*, 2007) and 80% of the world's hungry (UNDP, 2005). At the same time, changes in land-use and livelihoods in rural areas make it less straightforward to link rural areas with agriculture or food production. Given the association of climate vulnerability with poverty and food insecurity, and the number of people living in rural areas in developing countries, these areas are significant sites for vulnerability to climate change. Much of the literature reviewed in this chapter therefore reflects these conditions, in which rural development issues (especially in developing countries) are closely intertwined with the physical impacts of climate change and the vulnerability of rural populations.

The Fourth Assessment Report (AR4) of the IPCC contains no specific chapter on “rural areas”. Material on rural areas and rural people is found throughout the AR4, but rural areas are approached from specific viewpoints and through specific disciplines. Agriculture and food production, the impacts of which are assessed by Easterling *et al.* (2007), clearly take place mainly in rural areas, but that chapter was not able to cover impacts on other human activities taking place in rural areas or of significance to rural people. Many rural people follow livelihoods directly dependent on unmanaged or less-managed ecosystems, such as forests. However, the AR4 chapter on ecosystems (Fischlin *et al.*, 2007) was not able to cover the indirect impacts of ecosystem change on such livelihoods. The chapter on industry, settlement and society (Wilbanks *et al.*, 2007) reaches important conclusions about specific vulnerabilities of both urban and rural systems to climate change, but much of the literature reviewed and the most important conclusions, on high-density settlements, industry and infrastructure, are implicitly concerned with urban areas.

This chapter, under the general heading of “Human Settlements, Industry, and Infrastructure” assesses the impacts of climate change on, and the prospects for adaptation in, rural areas, seen as diverse patterns of settlement, infrastructure and livelihoods, in complex relations of interdependence with urban areas. Some of the key considerations will be as follows.

- Rural areas are largely defined in contradistinction to urban areas, but that distinction is increasingly seen as problematic.
- Rural areas are a spatial category, associated with certain patterns of human activity, but with those associations being subject to continuous change.
- Rural populations have, and will have, a variety of income sources and occupations, within which agriculture and the exploitation of natural resources have privileged but not necessarily predominant positions.
- Rural areas suffer from specific vulnerabilities to climate change, both through their dependence on natural resources and weather-dependent activities, and through their relative lack of access to information, decision-making, investment and services. Adaptation strategies will need to address these vulnerabilities.

The chapter will complement the treatment of issues also dealt with in Chapter 7 “Food Production Systems and Food Security” and Chapter 4 “Terrestrial and Inland Water Systems”, but will primarily look at how biophysical impacts of climate change on agriculture and on less-managed ecosystems translate into impacts on human systems (and in this regard will complement sections of Chapter 12 “Human Security”). It will also address issues dealt with in Chapter 12 “Human Security” and Chapter 13 “Poverty and Livelihoods”, but primarily from the point of view of

1 rural areas as spatial categories with particular characteristics. It will also draw out rural implications of climate
2 change in different regions as covered in chapters 23-29.

5 **9.1.2. Definitions of the Rural**

6
7 “Rural” and “rural areas”, in both policy-oriented and scholarly literature are terms often taken for granted or left
8 undefined, in a process of definition that is often fraught with difficulties (IFAD 2010). Ultimately, however, in
9 developing countries as well as developed countries, the rural is defined as the inverse or the residual of the urban
10 (Lerner and Eakin, 2010). Human settlements in fact exist along a continuum from ‘rural’ to ‘urban’, with ‘large
11 villages’, ‘small towns’ and ‘small urban centres’ not clearly fitting into one or the other. The populations of these
12 ambiguous settlements tends to range from a few hundred to approximately 20,000 inhabitants, with 20 to 40
13 percent of the population in many nations living in settlements in this category (Satterthwaite, 2006). The variations
14 in definitions from country-to-country can best be described through several examples (from both developed and
15 developing countries of different sizes):

- 16 • In Australia, “major urban areas” are defined as having a population of 100,000 and over; while “other
17 urban areas” have a population of 1,000 to 99,999. “Rural areas” included small towns with a population of
18 200 to 999. (Australian Bureau of Statistics n.d.).
- 19 • In India, urban areas are defined essentially as those with populations of 5,000 or more, or where at least
20 75% of the male working population is non-agricultural, or having a density of population of at least 400
21 people per km² (Government of India, 2012).
- 22 • In Jamaica, a place is considered to be urban if it has a population of more than 2,000 people and provides a
23 certain set of amenities and facilities that are deemed to indicate “modern living” (Statistical Institute of
24 Jamaica, 2012).
- 25 • In the United States, rural areas are defined by the Bureau of the Census as consisting of all territory
26 outside of defined urbanized areas and urban clusters, that is open country and settlements with fewer than
27 2,500 residents. Such areas can in practice have population densities as high as 999 persons per square mile
28 (386 persons/km²) (Womach, 2005).

29
30 Definitions of the rural are therefore variable between countries, recognized as problematic, and subject to various
31 attempts at refinement and sub-classification. While remaining aware of these issues, this chapter will in general
32 assess literature on current trends in rural areas, and on climate impacts, adaptation and vulnerability, using
33 whatever definitions of the rural are used in that literature.

36 **9.1.3. Between ‘Rural’ and ‘Urban’: the Peri-Urban Interface**

37
38 Authors have increasingly recognized that the simple dichotomy between ‘rural’ and ‘urban’ has “long ceased to
39 have much meaning in practice or for policy-making purposes in many parts of the global South” (Simon *et al.*,
40 2006:4). One approach to reconciling this is through the increasing application of the concept of “peri-urban areas”
41 (Simon *et al.*, 2006; Simon, 2008). These areas can be seen as rural locations that have “become more urban in
42 character” (Webster 2002: 5); as sites where households pursue a wider range of income-generating activities while
43 still residing in what appear to be “largely rural landscapes” (Lerner and Eakin 2010: 1); or as locations in which
44 rural and urban land uses coexist, whether in contiguous or fragmented units (Bowyer-Bower, 2006). A more
45 elaborate conceptualization is offered by the Bahasa Indonesian term *desakota*, which is used in academic literature
46 to incorporate recognition of the diversified economic systems that exist across the urban-rural spectrum, and the
47 closely interlinked, co-penetrating rural/urban livelihoods, communication, transport and economic systems
48 (Desakota Study Team 2008; McGee 1991; Moench and Gyawali 2008).

49
50 Peri-urban or *desakota* systems therefore incorporate a change in the type of relationships between human society
51 and ecosystems, and create shifts in the geographical and social distribution of risk and vulnerability (Pelling and
52 Mustafa, 2010). The characteristics of these regions can both increase and decrease disaster and climate risk, and
53 can pose both opportunities and challenges for disaster response and reconstruction (Pelling and Mustafa, 2010).
54 Increased transport connectivity in peri-urban areas can reduce disaster risk by providing a greater diversity of

1 livelihood options and improving access to education – but can also encourage land expropriation to enable
2 commercial development (hence increasing vulnerability of those who are made landless). Similarly, the expansion
3 of local labour markets and wage labour in these areas can strengthen adaptive capacity through providing new
4 livelihood opportunities – but can simultaneously increase disaster risk as reliance on wage labour can increase
5 dependence on the external economy and exposure to systemic shocks (Pelling and Mustafa, 2010: 7, Figure 2).
6

7 While there have been some assessments of “land degradation” and “sustainability” in peri-urban areas (e.g. Allen,
8 2006; Diaz-Chavez, 2006; Gough and Yankson, 2006; Binns and Maconachie, 2006), these have not yet focused on
9 how these areas will be affected by climate change, or how the process of peri-urbanization will shape vulnerability
10 or resilience. However, ecosystem services are particularly important in these areas, and environmental degradation
11 – again, including the impacts of climate change (Desakota Study Team, 2008) – will influence ecosystems services
12 and their role as a foundation for livelihood systems across developing countries in these systems, with particularly
13 important consequences for the poor.
14

15

16 **9.2. Findings of Recent Assessments**

17

18 Table 9-1 summarises key findings on rural areas from AR4 (particularly Easterling *et al.*, 2007 on agriculture,
19 Wilbanks *et al.*, 2007 on industry, settlement and society, and Klein *et al.* 2007 on links between adaptation and
20 mitigation), and relevant findings from the International Assessment of Agricultural Knowledge, Science and
21 Technology for Development (McIntyre, 2009). All these sources stress uncertainty, the importance of non-climate
22 trends, complexity and context-specificity, in any findings on rural areas and climate change.
23

24 [INSERT TABLE 9-1 HERE

26 Science and Technology for Development.]
27

28

29 **9.3. Assessing Impacts, Vulnerabilities, and Risks**

30

31 **9.3.1. Current and Future Economic, Social, and Land-Use Trends in Rural Areas**

32

33 Climate change in rural areas will take place against the background of the trends in demography, economics and
34 governance which are shaping those areas. While there are major points of contact between the important trends in
35 developing and industrialized countries, and the analytical approaches used to discuss them, it is easier to discuss
36 trends separately for the two groups of countries. In particular there is a close association in developing countries
37 between rural areas and poverty. Table 9-2 summarizes and compares the most important trends across the two
38 groups of countries. Figure 9-1, Table 9-3, and Figure 9-2 focus on two specific trends in developing countries:
39 demographic trends and trends in poverty indicators.
40

6 7 8 **9.3.2. Observed Impacts** 9

10 Documentation of observed impacts of climate change on rural areas involves major questions of detection and
11 attribution. Much discussion of vulnerability and adaptive capacity in rural areas, especially work based on
12 qualitative fieldwork at community level, reports local perceptions of climate change, or uses local meteorological
13 data without systematic attempts to distinguish between decadal trends and manifestations of anthropogenic climate
14 change (see for example chapters in Ensor and Berger, 2009, and Castro *et al.*, 2012). Similarly, impacts,
15 vulnerability and adaptive capacity are frequently discussed in the context of extreme events, and perceived
16 increases in their frequency, without systematic discussion of the difficulties of attributing extreme events to
17 anthropogenic climate change (see Paavola, 2008 as an example). Exposure to non-climate trends and shocks further
18 complicate the issue (Nielsen and Reenberg, 2010). Warner and van der Geest (submitted), use the UNFCCC
19 terminology of “loss and damage” for evidence of observed impacts of changes in monsoon patterns, drought,
20 flooding, coastal erosion and saline intrusion on rural livelihoods in nine countries in Africa, Asia and the Pacific,
21 but specify that the research methods employed do not allow attribution of climatic stressors to underlying causes
22 such as anthropogenic climate change. Box 18-4 of this report discusses the considerable potential of using
23 Traditional Ecological Knowledge to detect climate trends, but also the difficulties of using it to attribute trends to
24 anthropogenic climate change. Implied equivalence between perceptions, local decadal trends and global change is
25 not a problem in the context of detailed social-scientific analysis of vulnerability, adaptive capacity and their
26 determinants, but becomes more problematic if such work is implied to be evidence for observed impact.
27

28 The impacts of climate change on patterns of settlement, livelihoods and incomes in rural areas will be the result of
29 multi-step causal chains of impact. Typically, those chains will be of two sorts. One sort will involve extreme
30 events, such as floods and storms, as they impact on rural infrastructure and cause direct loss of life. The other sort
31 will involve impacts on agriculture or on ecosystems on which rural people depend. These impacts may themselves
32 stem from extreme events, from changing patterns of extremes due to climate change, or from changes in mean
33 conditions. The detection and attribution of extreme events is discussed by by the IPCC Special Report on Managing
34 the Risks of Extreme Events and Disasters to Advance Climate Change Adaptation (IPCC 2012, Seneviratne *et al.*,
35 2012). The detection and attribution of impacts on ecosystems and on agriculture are dealt with in Chapters 4 and 7
36 of this report. Both exercises are complex.
37

38 Seneviratne *et al.* (2012) give a detailed and critical assessment of the detection and attribution of observed patterns
39 of extreme events, which shows greatly varying levels of confidence in the attribution to climate change of global
40 and regional trends. For example they state that it is *likely* there has been a worldwide increase in extreme high-
41 water events during the late 20th century, and it is *likely* that there has been an anthropogenic influence on this. They
42 have *medium confidence* in detecting trends towards more intense and frequent droughts in some parts of the world
43 (Southern Europe and West Africa) since 1950. They note that opposite trends exist elsewhere, and that there is *low*
44 *confidence* in any trend in drought in, for example, East Africa, although other authors, such as Lyon and DeWitt
45 (2012) see a “recent and abrupt decline in the East African long rains” since 1999. Seneviratne *et al.* (2012) assign
46 *low confidence* to any observed long-term increases in tropical cyclone activity, or attribution of any changes in
47 cyclone activity to anthropogenic influence. They state that “attribution of single extreme events to anthropogenic
48 climate change is challenging” (2012:112).
49

50 Handmer *et al.*, (2012) discuss both observed and projected impacts of extreme events on human systems and
51 ecosystems. Numerous examples are given of observed impacts of extreme events – especially heatwaves, droughts
52 and floods – on water, ecosystems, and agriculture (particularly smallscale farming), though these are not explicitly
53 attributed to climate change. The impacts of droughts on African agriculture in recent decades are noted. Significant
54 impacts on settlement, infrastructure and tourism are discussed, though the major focus is on urban areas.

1
2 Important categories of extreme events causing negative impacts in rural areas include tropical storms and droughts:
3 Hurricane Stan in October 2005 affected nearly 600,000 people on the Chiapas coast as a consequence of flooding
4 and sudden river overflows (Saldaña-Zorrilla, 2008). Droughts produce severe economic distress in rural areas.
5 Employment reduction as a consequence of lower agricultural productivity and ultimate migration are two of the
6 most common responses (Gray and Muller, 2012). Ericksen *et al.* (2012) review a variety of livestock mortality
7 rates, up to 80% of livestock in some areas, for recent droughts in the Horn of Africa
8

9 Climate change impacts on agriculture and ecosystems run through rising temperature and changes in rainfall
10 variability and seasonality as well as through extreme events. Lobell *et al.* (2011) adopt a different approach to and
11 scale of analysis by examining global yields of the four major agricultural commodities, from 1980 to 2008, in
12 relation to temperature trends and in relation to a counterfactual without climate trends. Yields of maize and wheat
13 declined by 3.8 and 5.5% respectively relative to the counterfactual, which offset in some countries some of the
14 gains from improved agricultural technology. Badjeck *et al.* (2010) discuss current and future impacts on fisherfolk
15 across the world. Many local-level studies are subject to the attribution problems mentioned above, but Wellard *et*
16 *al.* (2012) cautiously note a convergence of climate data with the perceptions of farmers and officials to the effect
17 that over the last 30 years the rainfall in Malawi has become less predictable, that the rainy season is arriving later in
18 the year causing delays in planting of the main crops, and that damaging dry spells during the rainy season have
19 become more likely.
20

21 Glacial retreat in Latin America is one of the best evidenced current impacts on rural areas. In highland Peru there
22 have been rapid observed declines since 1962 in glacier area and dry-season stream flow, on which local livelihoods
23 depend, which accord well with local perceptions of changes that are necessitating adaptation (Orlove, 2009). Other
24 studies of the area focus both on observed changes in water availability and on glacial lake outburst floods, which
25 are attributable to climate change (Bury *et al.*, 2009; Carey, 2010, Carey *et al.* 2012). There is also a rich specialized
26 literature on the impacts of shrinking sea-ice and changing seasonal patterns of ice formation and melt on Inuit in
27 circumpolar regions (Ford, 2009; Beaumier and Ford, 2010).
28

29 Migration associated with weather-related extremes or longer-term climate trends is discussed in Chapter 12, Table
30 12-3, with empirical examples of migrations linked to droughts, coastal storms, floods and sea level rise. Attribution
31 of migration to climate change is extremely complex, as recognized by Black *et al.* (2011). Life in rural areas across
32 the world typically involves complex patterns of rural-urban and rural-rural migration, which are modified or
33 exacerbated by climate events and trends rather than solely caused by them. Black *et al.* (2011) see environmental
34 drivers of migration as operating in combination with economic, political, social and demographic drivers.
35 MacLeman and Hunter (2010), argue that analogies of historical migration trends associated with environmental
36 change though not with global climate processes, such as the 1930s Dustbowl in the USA (Reuveny (2007) allow
37 closer examination of such multiple causality.
38
39

40 **9.3.3. Future Impacts**

41

42 This section will examine the major impacts of climate change identified or projected for rural areas, under the
43 headings of: economic base and livelihoods; landscape and regional interconnections, including migration, trade,
44 investment and knowledge; and second-order impacts of climate policy. The following section, 9.3.4, assesses
45 literature on impact through a different and specific lens, that of economic valuation, though there is some overlap.
46 The biophysical impacts of climate change on food crops are dealt with primarily in Chapter 7; but also here and in
47 section 9.3.4 insofar as they affect rural economies. Biophysical impacts on non-food cash crops, in particular
48 beverage crops, are discussed below.
49

50 As with the observed impacts in section 9.3.2, the future impacts of climate change described here, and quantified in
51 section 9.3.4, are at the latter stages of complex causal chains that flow through changing patterns of extreme events
52 and/or effects of climate change on biophysical processes in agriculture and less-managed ecosystems. This
53 increases the uncertainty associated with any particular impact on the economic base, on land-use or on regional
54 interconnections.

1
2 Some of the discussion here will involve issues of vulnerability, particularly contextual vulnerability, but this is
3 discussed more fully in section 9.4 below.
4

5 6 9.3.3.1. *Economic Base and Livelihoods* 7

8 Climate change will affect rural livelihoods, or “the capabilities, assets (stores, resources, claims and access) and
9 activities required for a means of living” (Chambers and Conway, 1992). This is because many rural livelihoods are
10 dependent on natural resources (e.g. agriculture, fishing and forestry), and their availability will vary in a changing
11 climate. This may have effects on human security and wellbeing (Kumssa and Jones, 2010).
12

13 The livelihoods framework allows analysis of livelihoods outcomes as embedded within an external context of
14 multiple stresses and dynamics, all of which change over time (Kepe, 2008). Climate variability and change interacts
15 with, and sometimes compounds, existing livelihood pressures in rural areas, such as economic policy, globalization,
16 environmental degradation and HIV/AIDS, as has been shown in Tanzania (Hamisi *et al.*, 2012), Ghana (Westerhoff
17 and Smit, 2009), South Africa (O’Brien *et al.*, 2009; Ziervogel and Taylor, 2008; Reid and Vogel, 2006), Malawi
18 (Casale *et al.*, 2010), Kenya, (Oluoko-Odingoa, 2011), Senegal (Mbow *et al.*, 2008) and India (O’Brien *et al.*, 2004).
19

20 Especially for agriculture and other traditional livelihoods in developing countries, the concept of the “centrality of
21 the social” (Fairhead and Leach, 2006) is important: social relations within households (particularly gender
22 relations) and between households, profoundly affect production decisions, management of knowledge, and
23 marketing (Morton, 2007). Similarly access to diversification as an adaptation to climate extremes depends on
24 gender, age, governance and institutions, as shown in studies in South Africa, Tanzania and Uganda (Goulden *et al.*,
25 2009).
26

27 Morton (2007), adapting findings from AR4, suggests that the impacts of climate change on smallholder and
28 subsistence farmers can be conceptualized as a combination of: biological processes affecting crops and animals at
29 organism or field level; environmental and physical processes affecting production at a landscape, watershed or
30 community level; and other impacts, including those on human health and on non-agricultural livelihoods. This
31 schema is developed by Anderson *et al.* (2010), with a cross-cutting dimension of extreme events, increased
32 variability and shifts in average temperature and rainfall, as well as introducing indirect impacts, for example
33 through trade and food prices, and through climate mitigation policies.
34

35 An additional dimension is effects of climate change on water supply which in turn affect rural livelihood bases,
36 whether through a decrease or increase. In South Africa, for example, most of the climate change models predict a
37 reduction in freshwater availability by 2050, and a computable general equilibrium approach shows that this will
38 adversely affect household welfare (Juana *et al.*, 2008). In the Mount Kenya region, in contrast, the NRM3
39 Streamflow Model under the TGICA climate change projection will result in an increase of annual runoff by 26%,
40 with a severe increase in flood flows, and a reduction of the lowest flows to about a tenth of the current value
41 (Notter *et al.*, 2007). Changing rainfall levels will also affect groundwater levels, which play a role in rural
42 livelihoods. At the continental level in Africa, analysis of existing rainfall and recharge studies suggests that climate
43 change will not lead to widespread catastrophic failure of improved rural groundwater supplies (Macdonald *et al.*,
44 2009). However, at higher resolution groundwater resources are threatened (e.g. in South Africa, Knüppe, 2011),
45 and water crises are expected to multiple resulting from the increasing demand, and this will further affect the
46 people in rural areas who fetch water (Nkem *et al.*, 2011).
47

48 Water availability plays a key role in the viability of agricultural livelihoods, alongside changes in temperature.
49 Climate change is expected to impact water resources in the Asian region in a major way. A study by the World
50 Bank (2010a) argues that diminishing Himalayan glaciers would impact the agricultural water supply and food
51 security of more than one billion people in Asia. There are some regional and country studies, which support this
52 view. Likewise, Immerzeel *et al.* (2010) in a study of major river basins of the region viz. Indus, Ganges,
53 Brahmaputra, Yangtze and Yellow rivers conclude that different river basins would experience different impacts on
54 water availability and food security due to climate change. They further argue that the Brahmaputra and Indus basins

1 would be more susceptible to changes in water availability affecting the food security of 60 million people (ibid).
2 ADB (2009a) argues that climate change would increase water stress in four south East Asian countries of
3 Indonesia, Philippines, Thailand and Vietnam.
4

5 In assessing the impacts of climate change on water resources in rural areas of Europe, it is predicted that
6 Mediterranean climates will experience more pressure on water resources from reduced rainfall and meltwater from
7 glacial ice and snow. Schroter *et al.* (2005) predict that in the Mediterranean region summer water supply could fall
8 by 20 to 30% following global warming of 2°C and 40 -50% for 4°C . These declines would increase the costs of
9 production and living in the South (Falloon and Betts, 2010). Drought could threaten biodiversity and traditional
10 ecosystems particularly in Southern Europe with problems exacerbated by declining water quality. Decline in
11 economic activity may increase rural depopulation and harm the development of rural communities in Southern
12 Europe (Westhoek *et al.*, 2006). Given the rapid population growth, economic development and hence increasing
13 completion over water resources (for both agricultural and non-agricultural uses) in the Middle East, the per capita
14 availability of water will be reduced significantly for rural populations (see also Chapter 22) (Chenoweth J, *et al.*,
15 2011; Rochdane *et al.*, 2012; Iglesias *et al.*, 2010; Hanafi *et al.*, 2011, Sowers *et al.*, 2011; Verner, 2012: 166).
16 According to MacDonald *et al.* (2009) climate change will not lead to a widespread failure of improved rural
17 groundwater supply in Africa, but it could affect a population of up to 90 million people, as they live in rural areas
18 where annual rainfall is between 200 and 500mm per year, and where decreases in annual rainfall, changes in
19 intensity or seasonal variations may cause problems for groundwater supply.
20

21 Various studies conclude a decline in crop yield of agriculture due to climate change over the next three to four
22 decades in different parts of the world (Section 7.2.1, Chapter 7, AR5). For the Asia –Pacific region several studies
23 have concentrated on impacts emanating from the agricultural sector (ADB & IFPRI, 2009; ADB, 2009a; Srivastava
24 *et al.*, 2010; De Silva *et al.*, 2007; Xiong *et al.*, 2009, 2010; Ramirez-Villegas *et al.*, 2011) Similarly, studies on the
25 adverse impacts of climatic changes on yields in different parts of North America, Australia and Europe have been
26 conducted (Warren *et al.*, 2006; Olesena *et al.*, 2011; Anwar *et al.*, 2007; COPA COGECA, 2003; Schlenker and
27 Roberts, 2009; Roberts and Schlenker, 2010; Niemi *et al.* 2009; Wolfe *et al.* 2008). The impacts of climate change
28 on the smallholder and rain-fed dominated (96% of all agricultural land is rain-fed) agricultural sector are
29 considered to be very significant to the economies and livelihoods in Africa (Müller *et al.*, 2011; Kotir, 2011; Collier
30 *et al.*, 2008; Hassan, 2010). These results emerge across a range of scenarios. Several other studies also map
31 declines in net revenues from crops and the associated links with food security and poverty (Molua, 2009; Thurlow
32 *et al.*, 2009; Reid *et al.*, 2008; World Bank, 2010a; Thurlow and Wobst, 2003. Yield patterns are expected to present
33 spatial differences in South America, as projected by various studies with some losing such as bean growers in
34 Central America and some gaining such as sugarcane cultivators in Brazil. Such country case studies are based on
35 climate projections for SRES A2 and B2 scenarios derived by Hadley Center HadRM3P model (Pinto and Assad,
36 2008; ECLAC, 2009; ECLAC, 2010a). Adverse impacts on yield derived on the basis of simulations of the above
37 mentioned scenarios imply that since bean growers in Central America are small, low-income farmers, climate
38 change may have large repercussion throughout the region, endangering the food security of large segments of the
39 population (ECLAC, 2010b).
40

41 There will also be impacts on non-food cash crops, (or industrial crops), which represent an important source of
42 livelihood in many rural areas. However they have received less attention than traditional agricultural crops when
43 assessing the impacts of climate change. Relevant crops include cotton and other fibres, wine grapes, beverage
44 crops, and a wide variety of others. Yields of several cash crops in the Middle East such as olives, apples and
45 pistachios may decline if winter temperatures are too high (Verner, 2012). Literature on biofuels such as jatropa
46 focuses on the impacts of biofuels on climate change rather than on the effects of climate on yields and other
47 relevant variables in these agricultural systems. Where crops have dual use as food and biofuel (for example
48 oilseeds, sugarcane, sugar beet, maize and wheat) impacts can be inferred from studies that focus on their use for
49 food.
50

51 The findings of Easterling *et al.*, (2007), that cotton yields are likely to decrease as changes in temperature and
52 precipitation overcome potential benefits of increasing carbon dioxide have been corroborated in other studies,
53 where yield reductions have been estimated the order of 10% (Lee *et al.*, 2001) causing substantial economic losses.
54 It is reported that the cotton cultivation in Israel will declined by 52% and 38% under the A2 and B2 scenarios, and

1 that the net revenue will also decrease by 240% and 173% in the scenarios (Haim *et al.*, 2008: 433). Few systematic
2 assessments have been done on other fibre crops such as jute, kenaf, and flax.

3
4 Climate change impacts on wine grapes have been extensively studied and documented. Climate impacts such as
5 increasing number of hot days and decreasing frost risk may benefit some varieties. Lobell *et al.* (2006) assess the
6 impacts of climate change on yields of six perennial crops in California by 2099. This paper presents that the
7 production of wine grapes will experience relatively small changes compared to other commodities during the
8 concerned period. The uncertainty analysis shows the yield variations are limited within 10% although Gatto *et al.*
9 (2009) argue that the revenue of the industry in Napa, California could decline by 2034. Jones *et al.* (2005) indicate
10 that future climate change will exceed climatic thresholds affecting ripening for existing varieties grown at the
11 margins of their climatic limits. Warmer conditions could also lead to more poleward locations potentially becoming
12 more conducive to grape growing and wine production.

13
14 The case of tropical beverage crops, in particular coffee, is discussed in Box 9-1, and projected changes in area
15 suitable for all three tropical beverage crops are set out in Table 9-4.

16 _____ START BOX 9-1 HERE _____

17 **Box 9-1. Impacts of Climate Change on Tropical Beverage Crops**

18
19 The major traded beverage crops coffee, tea and cocoa support the livelihoods of several million small-scale
20 producers in over 60 countries of the tropics of Africa, Asia and Latin America. Coffee production has long been
21 recognized as sensitive to climate variability with global production and prices sensitive to occasional frosts in
22 Brazil – the world’s largest producer. Likewise the livelihoods of millions of small producers are dependent both on
23 stability of production and stability in world prices. During the last crash in coffee prices from 2000-2003 poverty
24 levels in the coffee growing regions of Nicaragua increased, while they fell in the rest of the country (World Bank,
25 2003); subsequently during the drought associated with El Nino in 2005 coffee productivity fell to between a third
26 and half of normal similarly leading to severely reduced income for small producers (Haggard, 2009).

27
28 Analysis of the effects of recent climate change on coffee producing areas in Mexico by Gay *et al.* (2006) show that
29 in Veracruz between 1969 and 1998 rainfall has decreased by 40mm and temperatures have increased by 0.02°C per
30 year. They developed econometric models of the relationship between coffee productivity and fluctuations in
31 temperature and precipitation, which gave an R-squared of 0.69 against historical data. Extrapolating the historical
32 tendencies in temperature and precipitation to 2020 and applying their econometric model they predict that coffee
33 production could decline by 34%, but most importantly this decline in production takes producers from making net
34 profits of on average around US\$200 per acre, to less than \$20 per acre. This has led to a series of studies projecting
35 the effects of climate change on the distribution of Arabica coffee growing areas of the coming decades summarized
36 below.

37
38 For Brazil, Pinto *et al.*, (2004) have mapped the changes in area suitable for coffee production in the four main
39 coffee producing states. A 3°C increase in temperature and 15% increase in rainfall (taken from the general
40 prediction of climate change for Southern Brazil in the IPCC 2001 report) would lead to major changes in the
41 distribution of coffee producing zones. In the main coffee producing states of Minas Gerais and Sao Paulo the
42 potential area for production would decline from 70-75% of the state to 20-25%, production in Goyas would be
43 eliminated, but only a 10% reduction in area in Parana. New areas suitable for production in Santa Catarina and Rio
44 Grande do Sul will only partially compensate the loss of area in other states (Pinto and Assad, 2008). The economic
45 impacts of a rise in temperature of 3°C would cause a 60% decline coffee production in the state of Sao Paulo equal
46 to nearly 300 million dollars income (Pinto *et al.*, 2007).

47
48 Models developed by CIAT predict the distribution of coffee under the A2a climate scenario using a statistical
49 downscaling of the climate change data from 20 different GCM models used in the IPCC Fourth Assessment. They
50 use WorldClim data to characterize the current distribution of coffee using 19 climatic variables and then use the
51 climate data downscaled to 1, 5 and 10 km resolution to map where those conditions may occur in the future (2020
52 or 2050). This method has been applied to coffee distribution in Kenya (CIAT 2010), Central America and Mexico
53
54

1 (Laderach *et al.*, 2010), tea production in Kenya (CIAT, 2011b) and Uganda (CIAT, 2011b), and cocoa production
2 in Ghana and Ivory Coast (CIAT, 2011c) (Table 9-4). Only one similar study appears to have been done for Robusta
3 coffee (Simonett, 2002) in Uganda, which appears to show similarly drastic changes in both distribution and total
4 area suitable for coffee production. At a minimum climate change will cause considerable changes in the distribution
5 of these crops disrupting the livelihoods of millions of small-holder producers, in many cases the total area suitable
6 for production would decrease considerably with increases of temperature of only 2-2.5°C. Although some local
7 areas may have improved conditions for coffee production, e.g. high altitude areas of Guatemala, the overall
8 predictions are for a reduction in area suitable for coffee production by 2050 in all countries studied.

9
10 _____ END BOX 9-1 HERE _____

11
12 [INSERT TABLE 9-4 HERE

13 Table 9-4: Projected changes in areas suitable for production of tropical beverage crops by 2050.]

14
15 Food security, which is also discussed in Chapters 7 and 13, is now known to reflect a broader range of factors than
16 merely food production (Sen, 1992). In three countries in Africa – Ethiopia, Malawi and Niger - mass mortality food
17 crises since 2000 -were triggered by a moderate decline in crop and/or livestock production, exacerbated by
18 “exchange entitlement failures” – food price spikes and asset price collapses (Devereux, 2009).). For example, the
19 food crisis of 2007-2008 exposed the vulnerability of rural livelihoods to external price shocks. Review of the
20 evidence shows that price rises have a disproportionate impact on the welfare of the poorest of the poor in rural
21 areas - female-headed households (which tend to be poorer than male-headed households) and those who have
22 limited access to land, modern agricultural inputs, infrastructure and education (Ruel *et al.*, 2009: 3). This has
23 illustrated that the vulnerability of rural livelihoods is affected by not only ecological, but also social and economic
24 factors that mediate or hinder people’s access to different assets and capacities to adapt (Ericksen, 2008a, b; Ellis,
25 2000: 290-91). However, changes in production will play a role in affecting food security and resultant increases in
26 malnutrition (Ringler, 2010).

27
28 Post-harvest aspects of agriculture – storage on farm and commercially, handling and transport – have been
29 relatively neglected in discussions of climate change, but will be affected by changes in temperature, rainfall,
30 humidity, and by extreme events. Many adaptation opportunities are already understood by postharvest service
31 providers, but getting postharvest knowledge into use at scale is a significant challenge (Stathers *et al.* submitted).

32
33 Rural food security is discussed extensively in the regional chapters of this report. Major themes include: for Africa
34 the range of contributing factors including globalization (22.3.3.1.5), and the adaptation responses of farmers
35 (22.3.3.16); for Asia (24.4.4) the regional variation in yields across crops and countries, and potential for adaptation;
36 for North America the high food insecurity in Mexico and the vulnerability to climate change of food security in
37 indigenous communities (26.6, 26.7); for Central and South America (27.3.4) the threats to the food security of the
38 poor in specific agricultural regions, and the inter-linkages between food and bioenergy and farmers’ responses.
39 Links between food security and agriculture trade are also discussed in 9.3.3.3 below.

40
41 Agricultural livelihoods are not restricted to crops, but also involve livestock in a variety of farming systems
42 (Devendra *et al.* 2005). Thornton *et al.* (2009) view the impacts on livestock of climate change as a neglected
43 research area, complicated by other drivers of change, broader development trends, rapid change in livestock
44 systems, spatial heterogeneity and social inequality between livestock-keepers. Drawing on livestock science, range
45 ecology and projected climate trends, they review some possible future impacts through quantity and quality of
46 feeds, heat stress, water, disease and others. Impacts through drought will be significant, as will heat stress,
47 particularly of *Bos taurus* cattle. Impacts through animal health and disease will be even harder to predict than other
48 categories of impact (Thornton *et al.*, 2009). Aggregating at the level of one country, Kabubo-Mariara (2009) shows
49 that livestock production in Kenya is highly sensitive to climate change, whereby increased mean precipitation of
50 1% could reduce revenues by 6%.

51
52 Pastoralists, who are dependent on livestock grazed in arid, semi-arid or mountainous areas, represent a specific
53 case, display very specific combinations of adaptive capacity, especially through mobility, and vulnerability, as
54 discussed in 9.3.5 below. Ericksen *et al.* (2012), with particular reference to East Africa, discuss possibilities of loss

1 of rangeland productivity, changes in rangeland composition towards browse species, and changes in herd dynamics
2 through more frequent droughts as possible impacts. In the Middle East, rangelands will be under substantial climate
3 stress which may reduce their carrying capacity, in light of the growing demand for meat products and the region's
4 growing size livestock population (Verner, 2012: 166). Little *et al.* (2001) discuss impacts of floods, directly and
5 through disease, on pastoral herds. Six SRES scenarios generated by six GCMs were used by Hein *et al.* (2009) for
6 the Ferlo Region in Northern Senegal, where livestock keeping is the main economic activity of the rural population.
7 A modest reduction in rainfall of 15% in combination with a 20% increase in rainfall variability could have
8 considerable effects on livestock stocking density and profits, reducing the optimal stocking density by 30%.

9
10 As extensive livestock production is associated with semi-arid areas marginal for cropping, some authors project
11 shifts toward livestock production under climate change. Jones and Thornton (2009) identify major transition zones
12 across Africa where increased probability of drought between now and 2050 will create conditions for shifts from
13 cropping to livestock. Data from over 9000 African livestock farmers in 10 countries shows that farmers are more
14 likely to have livestock as temperatures increase and as precipitation decreases, based on logit analysis to estimate
15 whether farmers adopt livestock, followed by three econometric models to determine species choice. These analyses
16 predict a decrease in the probability of beef cattle and an increase in the probability of sheep and goats, and more
17 heat-tolerant animals will dominate the future in Africa (Seo and Mendelsohn, 2007a). A development of the
18 Ricardian method shows that these choices relate to the net income of different animal species. On this basis, large-
19 scale commercial beef cattle farmers are most vulnerable to climate change in Africa, particularly since they are less
20 likely to have diversified (Seo and Mendelsohn, 2007b). To Sallu *et al.* (2010), investment in and accumulation of
21 physical assets, including land and livestock, can be a strategy to decrease vulnerability

22
23 Livelihoods dependent on fisheries will also experience vulnerability to climate change. Impacts of climate change
24 on aquatic ecosystems will have adverse consequences for the world's 36 million fisherfolk as well as the nearly 1.5
25 billion consumers who rely on fish for more than 20% of their dietary animal protein (Badjeck *et al.*, 2010). An
26 indicator approach showed that economies with the highest vulnerability of capture fisheries to climate change were
27 in Central and Western Africa (e.g. Malawi, Guinea, Senegal, and Uganda), Peru and Colombia in north-western
28 South America, and four tropical Asian countries (Bangladesh, Cambodia, Pakistan, and Yemen)(Allison *et al.*,
29 2009). This vulnerability arises from the combined effect of predicted climate change on fish stocks, the relatively
30 high share of fisheries as a source of income (including export earnings) and diets, and limited societal capacity to
31 adapt due to the prominence of poverty in these societies (Allison *et al.*, 2009). In another study of changes in
32 climate and social systems in north eastern Asia on fisheries development, Kim (2010) argues that in countries like
33 China, Japan and South Korea these changes could have a negative impact on fisheries adversely affecting
34 livelihoods and food security of the region. (Chapter 7, AR5, provides an assessment of the impacts of climate
35 change on the biological and ecological processes in aquatic ecosystems and on livelihoods that depend on the
36 fisheries and aquaculture sector).

37
38 Diversification into non-farm incomes might accelerate if climate-related risks of farm income failure increase as a
39 result of climate change, although it is also determined by other factors such as poverty, income distribution, farm
40 output, gender, labour and credit markets (Ellis, 2000). Such diversification would help households achieve low risk
41 correlations between their livelihood components (Ellis, 2000).

42 43 44 9.3.3.2. *Infrastructure*

45
46 Assessments of the impacts of climate change on infrastructure take a general or urban perspective and do not focus
47 on rural areas, though rural impacts can be inferred. For example, river flooding and sea level rise will produce
48 temporary loss of land and land activities, and transportation infrastructure particularly on coastal areas (Kirshen et
49 al 2008). Climate change will affect current water management practices and the operation of existing water
50 infrastructures, which are very likely to be inadequate to overcome the negative impacts of climate change on water
51 supply reliability (Kundzewicz *et al.*, 2008). Some documented impacts on dams, reservoirs and irrigation
52 infrastructure are: reduction of sediment load due to reductions in flows (associated with lower precipitation), this
53 positively affects infrastructure operation (Wang *et al.*, 2007); impacts of climate variability and change on storage
54 capacity that creates further vulnerability (Lane *et al.*, 1999); and failures in the reliability of water allocation

1 systems (based on water use rights) due to reductions of streamflows under future climate scenarios (Meza *et al.*,
2 2012).

5 9.3.3.3. *Spatial and Regional Interconnections*

6
7 In both developing and developed countries, rural areas have been increasingly integrated with the rest of world. The
8 main channels through which this rapid integration process takes place are migration (permanent and cyclical),
9 commuting, transfer of public and private remittances, regional and international trade, inflow of investment and
10 diffusion of knowledge through new information and communication technologies (IFAD, 2010), as well as the
11 spatial intermingling of rural and urban economic activities, labelled as *desakota* systems and discussed in Section
12 9.1.3 above. A trend to increase in urban areas can be associated with different spatial patterns, reflecting alternative
13 development processes, e.g. periurbanisation versus counter-urbanisation (Rounsevell *et al.*, 2007). In this context,
14 changes in the occurrence of some types of extreme events due to climate change, increased variability, and
15 changing mean climate parameters are *likely* to have significant implications for regional and global integration
16 trends in rural areas.

19 9.3.3.3.1. *Migration*

20
21 Growing efforts are researching environmental migration, building on the AR4 conclusion that extreme events might
22 lead to changed patterns of migration (Boko *et al.*, 2007). Though the impacts of climate change are *likely* to affect
23 population distribution and mobility, it is difficult to establish a causal relationship between environmental
24 degradation and migration, which is still termed “complex and unpredictable” (Brown, 2008). Hence, the link
25 between internal migration and environmental stresses is contested. One school of thought shows migration (and
26 particularly rural out-migration) increasing during times of environmental stresses (e.g. Afifi, 2011; Gray and
27 Mueller, 2012), with projections that these trends will continue under climate change (Kniveton *et al.*, 2011). This
28 may also affect human security (Brown and Crawford, 2008). Growing vulnerability to environmental change may
29 also lead to an increase in abandonment of settlements (McLeman, 2011).

30
31 However, some estimates and forecasts of the potential number of displaced people because of climate change are
32 being challenged by another body of literature which argues that migration rates are no higher under conditions of
33 environmental or climate stress (Black, 2011; van der Geest, 2011; van der Geest and de Jeu, 2008; Tacoli, 2009;
34 McLeman and Hunter, 2010; Gemenne, 2011; Foresight, 2011; Cohen, 2004; Brown, IOM, 2008). Some studies
35 have ascertained (Mertz *et al.*, 2007; Parnell and Walawege, 2011) that climatic variability is certainly one of the
36 most significant catalyst for migration toward urban areas, as has been the case during the severe droughts occurred
37 in the Sahel in the 70s and the 90s, but the current alarmist predictions of massive flows of refugees (so called
38 “environmental refugees” or “environmental migrants”), are not supported by past experiences of responses to
39 droughts and extreme weather events and predictions for future migration flows are tentative at best (C. Tacoli,
40 2009; M’bow 2011). Similarly, a recent survey by Mertz *et al.* (2010) has argued that climate factors play a limited
41 role in past adaptation options of sahelian farmers.

42
43 There have also been attempts to understand the nexus between migration and climate change through examining
44 analogous experiences in the past and present in which climate variability is associated with particular kinds of
45 population movements (McLeman and Hunter 2010). For example, in Ghana the causality of migration was
46 established to be relatively clear in the case of sudden-onset environmental perturbations such as floods, whereas in
47 case of slow-onset environmental deterioration, there was usually a set of overlapping causes - political and
48 socioeconomic factors – which come into play (van der Geest, 2011). Given the multiple drivers of migration (Black
49 *et al.*, 2011) and the complex interactions which mediate migratory decision-making by individual or households
50 (Raleigh, 2008; McLeman and Smit, 2006; Kniveton and Al., 2011, Blake and Al, 2011), the detection of the effects
51 of climate change on intra-rural and rural-to-urban migration remains a major challenge.

9.3.3.3.2. *Trade*

Although agricultural exports accounted for only one sixth of world agricultural production and consumption (Anderson, 2010), it is the sector for which most data is available, and is the focus here. Between 2000 and 2008, the value of global agricultural exports rose from US\$ 551 billion to US\$ 1,342 billion, representing an average annual growth of 5 percent (WTO, 2009). In addition to trade in primary crops, trade in processed food, fish and forest products has also been expanding (WTO, 2009). However, the fundamentals of agricultural trade have changed significantly in the late 2000s. There was a major agricultural price spike, and historically high degree of price volatility towards the end of the period. Some cyclical and structural factors – such as droughts in several major producers, including Australia, Ukraine and the United States, creating shortage of cereals in international markets, the expansion of bio-fuels at the expense of food crop production, export controls, growing demand by emerging economies for secondary agricultural products such as meat, energy and feed crops, financial speculation – have led to a volatile and unpredictable trading environment (FAO, 2008; Timmer, 2010; Schmidhuber and Matuschke, 2010; Karapinar and Haberli, 2010; Headey, 2011).

Against this backdrop, climate change is expected to affect the pattern and volume of international agricultural trade flows. At the sectoral and product levels, it may alter the comparative advantage of countries and regions through its potential impacts on their agricultural supply capacities. These effects will be reflected on agricultural prices – which are the signals of economic scarcity or abundance. Recent studies produce even more pessimistic projections of climate change on food prices differentiated at the crop level than did AR4 (Easterling *et al.*, 2007). For example, simulations results of two climate models – the National Centre for Atmospheric Research, US (NCAR) and the Commonwealth Scientific and Industrial Research Organization, Australia (CSIRO) – based on A2 scenario inputs – suggested that climate change might result in additional price increases in 2050, ranging from 30-37 percent for rice, 52-55 percent for maize to 94-111 percent for wheat (Nelson *et al.*, 2009). If CO₂ fertilization is taken into account, the 2050 price increases are expected to be smaller (for example, by 15-17 percent for rice relative to no CO₂ fertilization). It is important to note that these price increases are projected in addition to the price increases (62 percent in rice, 63 percent maize, and 40 percent in wheat) that are expected under no-climate-change scenario, which are largely driven by population and income growth projected to be greater than productivity and area growth (Nelson *et al.*, 2009a). Other studies, using different models and scenario combinations, produce significantly different results in relation to price projections. For example, IFPRI using the International Model for Policy Analysis of Agricultural Commodities and Trade (IMPACT) estimates additional price increases for 2050 (relative to no-climate change) of 32- 34 percent for maize (with baseline and pessimistic scenarios in relation to population and income growth (e.g. human well-being)), 18-20 percent for rice (with optimistic and pessimistic human well-being scenarios) and 23-24 percent for wheat (with baseline and pessimistic human well-being scenarios) (Rosegrant, *et al.*, 2008; Nelson *et al.*, 2010). This reflects the high level of uncertainty on price predictions (Rivera-Ferre and Ortega-Cerdà, 2011) and the caution needed to develop food policies.

The prices of beef, pork and poultry are also projected to increase significantly under A2 inputs simulated in CSIRO and NCAR models. Accordingly, in addition to the projected price increases, under no-climate-change scenario, of 33%, 36%, 35% for beef, pork and poultry respectively, 20%, 18%, 21% increases are projected for 2050 under climate change scenario for these three commodities respectively, without taking into account CO₂ fertilization (Nelson *et al.*, 2009a).

The projected production and price changes across regions will affect trade flows substantially. Without climate change, net developed-country exports (of rice, wheat, maize, millet, sorghum, and other grains) to developing countries are expected to increase by 22.4 million mt, from 83.4 million mt to 105.8 million mt between 2000 and 2050, representing a growth of 27 percent (Nelson *et al.*, 2009b). Climate change might lead to an additional export volume of 0.9 million mt (with wetter NCAR scenario) to 39.9 million mt (with drier CSIRO scenario) (Nelson *et al.*, 2009b). Developed-country exports are projected to increase by an additional 12 to 18 percent relative to no climate change if CO₂ fertilization is taken into account (Nelson *et al.*, 2009b). Regions such as South Asia, East Asia and Pacific are projected to increase their imports substantially over this period. For example, South Asia which exported around 15 million mt in 2000 is expected to import up to 54 million mt (with drier CSIRO scenario) (Nelson *et al.*, 2009b). By 2050, the Middle East and North Africa region and Sub-Saharan Africa which are already net importers of cereals are estimated to increase the volumes of cereals imports by 29 and 30 percent, respectively

1 (Nelson *et al.*, 2009b). In addition, due to climate impacts on prices, trade flow values will increase even at higher
2 rates than trade volumes.
3

4 However, there are other models producing substantially different projections for developed country cereals exports.
5 For example, MIROC scenario (produced by the Center for Climate System Research, University of Tokyo) with
6 A1B-induced production effects on U.S. maize production project a radical decline in net maize exports by up to 70
7 percent by 2050 (Nelson *et al.*, 2010). This is in sharp contrast to the projection that U.S. exports would double
8 under no-climate change scenario (Nelson *et al.*, 2010). These different projections underline the high degree of
9 uncertainty in the climate scenarios.
10

11 The literature highlights the potential role of international trade in managing the effects of climate change on
12 agricultural productivity (Nelson *et al.*, 2009; Huang *et al.*, 2011:12; Jankowska, et al 2012). Models show that
13 world trade volumes would need to increase substantially to offset the negative welfare effects of climate-change
14 induced crop yield variability (Reimer and Li, 2009). This would also allow some countries to capitalize on new
15 export opportunities arising from higher achievable yields, for example in Argentina (Asseng *et al.*, 2013) or
16 increasing heterogeneity of climate impacts on yields, for example in Tanzania (Ahmed *et al.*, 2012). Similarly, it is
17 projected that climate-induced food deficits occurring in low income developing countries will be supplied, fully or
18 partly through food aid. Hence food aid agencies, which have already been struggling to deliver aid in an
19 environment of growing scale of poverty and malnutrition due to the recent price hikes and of historical volatility in
20 food aid supplies might face additional operational challenges (Barrett and Maxwell, 2006; Harvey *et al.*, 2010).
21 Staple food trade might also save water resources, and hence contribute to adaptation efforts in rural areas, as the
22 total volume of embedded water (“virtual water”) in trade is projected to decrease under climate change (Konar *et*
23 *al.*, 2013).
24

25 The potential role that trade could play in managing the impacts of climate change will inevitably be affected by
26 countries’ trade policies. For example, during the ‘food crisis’ of 2007–2008, dozens of countries instituted various
27 forms of export restrictions on food staples, in order to maintain domestic availability of supplies, which created
28 additional volatility in global markets (Anderson and Nelgen, 2012; Headey, 2011; Karapinar, 2011, 2012). Low-
29 income countries are particularly vulnerable to such volatilities (FAO, 2008; Reimer and Li, 2009).

30 The emerging literature on the subjects illustrates that deepening agricultural markets through trade reform,
31 improved market access, and institutional efforts to improve the predictability and the reliability of the world trading
32 system as well as by investing in additional supply capacity of small-scale farms in developing countries could help
33 reduce market volatility and offset supply shortages which might be caused by climate change (UNEP, 2009; WTO,
34 2009; Nelson *et al.*, 2009a and 2009b; Reimer and Li, 2009; Ahmed *et al.*, 2012).
35
36

37 9.3.3.3.3. *Investment* 38

39 Climate change may also affect investment patterns in rural areas. On the one hand, countries, regions and sectors
40 that are expected to be affected adversely by climate change may have difficulty attracting investment. On the other
41 hand, ecological zones that will become favourable due to climate change are expected to see increasing inflow of
42 investment. For example the recent price hikes in agricultural commodities have led to new initiatives of foreign
43 direct investment (FDI) in the form of large-scale crop production in poor countries (Anseeuw *et al.*, 2012; World
44 Bank, 2010). This type of FDI seems to follow a new pattern whereby capital-endowed countries with high imports
45 of food or feed crops are preparing to invest in large production projects in low-income countries endowed with
46 low-cost labour force, land and water resources. Climate change may lead to similar investment patterns. However,
47 there is a risk that these new investments might not be integrated into local structures and the local populations
48 becoming increasingly vulnerable as they might lose access to vital assets such as land and water (Anseeuw *et al.*,
49 2012). On the other hand, if FDI comes with a basket of new technology, business connections, infrastructure and
50 human capital, and if such investments lead to local business development and employment generation, they could
51 bring substantial benefits to the host country (World Bank, 2010).
52
53
54

1 9.3.3.4. *Knowledge*

2
3 Rural areas, as never before, are exposed to diffusion of knowledge through migration, trade and investment flows,
4 technology transfers, and improved communication and transport facilities (IFAD, 2010), although differentials in
5 knowledge access between rural and urban areas remain. Future impacts of climate change on these channels of
6 integration will affect the pace and intensity of knowledge transfers. For example, increased transport and
7 communication connectivity can reduce disaster risk by providing a greater diversity of livelihood options and
8 improving access to education (Pelling and Mustafa 2010). If trade, migration and investment flows will be
9 intensified as a result of climate change, this will inevitably have a positive impact on knowledge transfer both from
10 and to rural areas.

11
12 Traditional Ecological Knowledge (TEK and also known by a variety of other terms), developed to adapt to past
13 climate variability and change, can both be impacted by climate change and used and transformed in adaptation
14 (Nyong, *et al.*, 2007). Ettenger (2012) discusses how seasonal hunting camps among the Cree of Northern Quebec
15 that were the occasion for intergenerational knowledge transfer have been disrupted by changing bird migrations,
16 while new technologies such as the internet, GPS and satellite phones have been integrated into livelihood strategies.
17 Climate-change induced migration can threaten LTK transfer (Valdivia *et al.*, 2010; Giles *et al.*, 2013). Disaster
18 management by central government may undermine decentralization efforts, disfavoring TEK transfer (Dekens,
19 2008).

20
21
22 9.3.3.4. *Second-Order Impacts of Climate Policy*

23
24 Policy responses to climate change impact on rural people and can affect their livelihoods and environment. The
25 need to work towards increasing energy supply from renewable resources as responses to climate change, will in
26 time manifest themselves in landscape changes, whether it be through the granting of planning consents for wind
27 farms, the creation of a market for energy crops, structural changes in coastal defences, etc. (Dockerty *et al.*, 2006),
28 or increased employment opportunities (del Río and Burguillo, 2008).

29
30 Social responses to these changes are expected (Molnar 2010) while some impacts have already been documented.
31 One of the most analysed is the promotion of biofuel crops, which have been an extremely controversial issue in the
32 last decade. Delucchi (2010) concludes that biofuels produced from conventional intensive agriculture will
33 exacerbate stresses on water supplies, water quality, and land use, and thus will have impacts on rural areas (land-
34 use change) and agriculture. Concerns have already been expressed about the impact of biofuel production on food
35 security due to increase in food prices, increasing land concentration (and landgrabs), and competition for water
36 (Eide, 2008; Müller *et al.*, 2008). Gurgel *et al.* (2007) modeled potential production and implications of a global
37 biofuels industry: estimated production at the end of the century will reach 220-270 exajoules in a reference
38 scenario, and 320-370 exajoules under a global effort to mitigate greenhouse gas emissions. They recognise the need
39 for a high land conversion rate to achieve this. Delucchi (2010) suggests developing biofuels programs with low
40 inputs of fossil fuels and chemicals, that do not require irrigation, and that use land with little or no economic or
41 ecological value in alternative uses (Plevin *et al.*, 2010). This implies analysing each case in its context, including
42 production for both local and global markets.

43
44 Another relevant climate-policy developed in the last few years under the UNFCCC umbrella has been the REDD
45 mechanisms. Major criticisms of this instrument arise from the difficulties posed for the participation of
46 communities in REDD programs and its potential in undermining a general decentralization of forest management
47 (Phelps, Webb, and Agrawal 2010), which is shown to be essential for a sustainable management of forests and
48 reducing vulnerability of forest-dependent communities. Campbell (2009) notes the presence of some synergies
49 between mitigation through REDD and adaptation, but also trade-offs between REDD, rural incomes, and rural
50 equity. To address these problems Sikor *et al.*, (2010) suggest the recognition and operationalizing of forest peoples'
51 rights through participation of communities in decision-making, equitable distribution of forest benefits, and
52 recognition of their particular identities. This will require the implementation of a polycentric approach implying a
53 nested forest and climate governance.

9.3.4. Valuation of Climate Impacts

This section assesses literature on climate change impacts through studies that have adopted various economic methods for valuation of impact. Valuation of impacts of climate change on rural areas is a difficult task and should reflect the significance of the ecological service categories for different stakeholders, including women (Kennet 2009) and minority groups, and ideally the valuations of unit changes in the levels of those services across management options. Valuations can be made at individualistic or communal levels (Farber *et al.*, 2006). different understandings of value may exist (Spangenberg and Settele, 2010; Kosoy and Corbera, 2010), as well as different philosophical approaches to address it (from positivists to ethicists) (Weisbach and Sunstein, 2008), which makes more difficult to agree on valuation methodologies. The impacts of climate change are expected to be unequally distributed across the globe, with developing countries at a disadvantage, given their geographical position, low adaptive capacities (Stern, 2007; World Bank, 2010a) and the significance of agriculture and natural resources to the economies and people (World Bank, 2010b; Collier *et al.*, 2008). Both direct and indirect impacts have been projected, such as lower agricultural productivity, increase in prices for major crops and rise in poverty (Hertel *et al.*, 2010), which have implications for rural areas and rural communities. This section discusses literature on the valuation of impacts as relevant for rural areas and arising from climate change, with reference to agriculture, fisheries and livestock, water resources, GDP and rural economy, extreme weather events and sea level rise and health. There are various channels through which changes in economic values may occur in rural areas, such as through changes in profitability, crop and land values and loss of livelihoods of specific communities through changes in fisheries and tourism values. Losses and gains in health status and nutrition, and wider economy-wide impacts such as changes in job availability and urbanization also impact economic values that accrue to rural communities, the opportunities and the constraints that rural communities experience and changes that rural landscapes undergo. The impact on availability of fresh water resources is another major area of concern for the developing regions in particular. Climate change can adversely impact poverty through multiple channels (Section 10.9, chapter 10, AR5).

Viewing impacts regionally, despite the ongoing debates around the uncertainty and limitations of valuation studies, scholars generally agree that African countries could experience relatively high losses compared to countries in other regions (World Bank, 2010b; Watkiss *et al.*, 2010; Collier *et al.*, 2008). These conclusions emerge across a range of climate scenarios and models used by researchers. For instance, Watkiss *et al.* (2010) use the FUND model for a business as usual scenario and a mitigation 450ppm 2 degrees scenario as generated by using the PAGE2002 model, while the World Bank uses a range of country specific models for calculating costs. Overall negative consequences are seen for Africa and Asia, due to changes in rainfall patterns and increases in temperature (Müller *et al.*, 2011). Though climate change and climate variability would impact a range of sectors, water and agriculture are expected to be the two most sensitive to climatic changes in Asia (Cruz *et al.*, 2007, Chapter 3 AR5) and for droughts in particular for Australia (Nelson *et al.*, 2007, Meinke and Stone 2005). In South American countries, higher temperatures and changes in precipitation patterns associated with climate change affect the process of land degradation, compromising extensive agricultural areas in LAC countries. Research on climate change impacts in rural North America has largely focused on the effects on agricultural production and on indigenous population, many of whom rely directly on natural resources. Developed countries in Europe will be less affected than the developing world (Tol *et al.*, 2004), with most of the climate sensitive sectors located in rural areas.

Valuation and costing of climate impacts, draws upon both monetary and non-monetary metrics. Most studies use models that estimate aggregated costs or benefits from impacts to entire economies, or to a few sectors, expressed in relation to a country's gross domestic product (GDP) (Stage, 2010; Watkiss, 2011). Values which are aggregated across sectors generalise across multiple contexts and could mask particular circumstances that could be significant to specific locations, while expressing outcomes in aggregated GDP terms. This is a matter of concern for economies in Africa and Asia, where subsistence production continues to play a key role in rural livelihoods. Valuation of non marketed ecosystem services poses further methodological and empirical concerns (Dasgupta, 2008; Dasgupta *et al.*, 2009; Watkiss, 2011; Stage, 2010). Würtenberger *et al.* (2006) developed a methodology to estimate environmental and socio-economic impacts of agricultural trade regarding virtual land use, and Adger *et al.* (2011) use qualitative methodologies to consider non-market and non-instrumental metrics of risk, based on

1 principles of justice and recognition of individual and community identity, which they suggest should be considered
2 in decision-making.

3
4 Integrated assessment models and cost-benefit tools have been criticised for not being a valid tool to assess
5 intergenerational events, processes with high levels of uncertainty and irreversibility, for not considering equity
6 concerns, power structures, or for assigning monetary values on the basis of incomplete information or assuming
7 speculative judgments regarding the monetary value of, e.g. natural resources (Ackerman et al. 2009; Toman 2006;
8 Kuik *et al.*, 2008), not recognising incommensurability (Aldred 2012). In recent years, various perspectives for
9 valuing the economic impacts of climate change have come into focus including the feminist (Nelson 2008; Power
10 2009), deliberative (Zografos and Howarth 2010) or behavioural economics (Brekke and Johansson-Stenman 2008;
11 Gowdy 2008), and the integration of economics with moral and political philosophy (Dietz *et al.*, 2008). Some
12 common characteristics of these new approaches include transdisciplinarity, acknowledging the diversity of views
13 and maintaining complexity in models. Research in this area although relatively recent, shows promise.

14
15 Illustrative regional and sub-regional estimates for the value of impacts of climate change are presented here.
16 Estimates for agriculture in most cases relate directly to rural lives. A range of other impacts on which available
17 information exists is also considered, since these values and costs concern significant proportions of livelihoods and
18 assets in rural areas. It is also to be noted that available literature concentrates on certain sectors and a few countries.
19 For instance, research on specific rural populations is less developed than for particular sectors that are largely
20 located in rural spaces such as agriculture. Limited information is available on West Asia and Pacific islands, on
21 health impacts for both Africa and Asia, small and poor communities of the Arctic (Furgal and Seguin 2006, Furgal
22 and Prowse, 2008; Ford and Pearce, 2010).

23 24 25 9.3.4.1. *Agriculture*

26
27 Changes in agricultural production will have corresponding impacts on incomes and wellbeing of rural peoples. The
28 largest known economic impact of climate change is upon agriculture because of the size and sensitivity of the
29 sector, particularly in the developing world and to a lesser extent in parts of the developed world. A large number of
30 studies to evaluate the impacts on the agricultural sector and its ramifications for communities have been conducted
31 at various scales, ranging from micro level farm models to large scale regional and country level climate cum socio-
32 economic scenario modeling exercises. Some of these also report values for associated economic losses. Since
33 models are simplifications of complex real world phenomena, different models tend to highlight different aspects of
34 impacts and their consequent economic values. For instance, in estimating economic losses the Ricardian method
35 has been used widely to study climate change impacts in agriculture and inbuilt adaptation. However, often such
36 analysis does not incorporate features like technological progress, relative price changes, agricultural policy and
37 other dynamic characteristics. Similarly on the bio-physical impacts side, changes in the El Niño/Southern
38 Oscillation (ENSO) statistics may also have serious economic implications for the agricultural sector in certain
39 countries such as in Latin America and Australia (Kokic *et al.*, 2007). However, ENSO responses differ strongly
40 across climate models, and at the current stage of understanding do not allow conclusions to be drawn on how global
41 warming will affect the Tropical Pacific climate system (Latif and Keenlyside, 2009). A sample of the available
42 studies is provided in Table 9-5.

43
44 [INSERT TABLE 9-5 HERE

45 Table 9-5: Illustrative sample of studies on economic value and changes in value from climate change.]

46 47 48 9.3.4.2. *Other Rural Sectors: Water, Fisheries, Livestock, Mining*

49
50 The changes in valuation of water resources due to climate change arise from expected impacts on populations
51 dependent on these water resources and these will be felt in several parts of the world (Sections 3.4.9, 3.5 and 3.8,
52 Chapter 3, AR5). Monetary estimates of losses due to impacts on water resources are not generalizable. Among
53 alternative approaches to value water resources, use of the water footprint tool (Hoekstra and Mekonnen, 2012) and

1 the concept of virtual water has been suggested for informing policy-makers in water-scarce countries, such as
2 Egypt.

3
4 Analysis of intergenerational valuation has shown to provide some interesting results in valuation of marine fisheries
5 (Ainsworth and Sumaila 2005). For fisheries in rural coastal areas, some of the challenges faced include the
6 valuation of environmental externalities such as breeding habitats, or mangroves, that might be lost due to climate
7 change or other forces (Hall 2011). It has also been argued that the true worth of livelihoods dependent on fisheries
8 in developing countries, where these constitute part of a diversified livelihood or subsistence strategy, requires a
9 different set of metrics from those used in the developed world (Mills et al. 2011). Climate change can also have
10 significant impacts on livestock keeping (Section 9.3.3.1 current chapter). Franco *et al.* (2011) reveal significant
11 declines in forage for ranching in California under SRES scenarios B1 and A2. The dairy sector in California is
12 predicted to lose \$287-902 million annually to climate impacts by the end of the century (Lal *et al.*, 2011).

13
14 A relatively less researched area which may impact the livelihoods of rural communities is mining (Section
15 26.11.1.2). Pearce *et al.* (2011) highlight the current and ongoing vulnerability of mining and mining communities in
16 Canada, often rural and with few other economic activities, to climate change. Current and past infrastructure for
17 mines was built under a no-climate change presumption and economic and ecological vulnerabilities as a result are
18 substantial, and industry actors are unprepared to deal with this. As with other industrial sectors, the extent of loss
19 would vary depending on the importance of the sector in the local economy (Backus *et al.*, 2012).

20 21 22 9.3.4.3. GDP and Economy-Wide Impacts

23
24 In a regional review of economics of climate change in four south East Asian countries of Indonesia, Philippines,
25 Thailand and Vietnam, ADB suggests that climate change would result in a mean annual loss of 2.2% of GDP by
26 2100 if only market related impact is accounted. If non market impacts related to health and ecosystems are also
27 accounted for, then it would result in 5.7% annual loss of GDP for the same period (ADB, 2009a). Bigano *et al.*
28 (2008) suggest that a predicted 25cm rise in sea level alone would result in a GDP loss of 0.1% in southeast Asia by
29 2050. Another estimate suggests that four Asian countries of Bangladesh, India, Philippines and Vietnam had a
30 cumulative loss of \$20billion due to natural disasters in the last decade, which makes them quite sensitive to climate
31 risks (ADB, 2009 b). In case of Bangladesh, which is extremely vulnerable to climate change because of a large area
32 less than 5 metres above sea level, a single severe cyclone could result in damages worth \$9 billion by 2050
33 accounting for 0.6% of the country's GDP (ADB, 2009b). Most of the impacted regions are rural, and coastal. Thus
34 the implied losses in GDP become relevant for the rural communities in these countries.

35
36 Coastal and island rural communities throughout North America are less able to afford major infrastructure
37 improvements and will thus be more vulnerable to the effects of sea level rise, including waterborne and food borne
38 diseases, water table salinity, and diminished storm protection from affected reefs and wetlands, but detailed costs
39 are very site-specific (Hess *et al.*, 2008). Cordalis *et al.* (2007) discuss the climate vulnerabilities and policy
40 complexities facing Native American tribes and note that moving villages where needed could cost billions of
41 dollars.

42
43 In Arctic Canada and Alaska, infrastructure built for very cold weather will deteriorate as the air and ground warm.
44 Larsen *et al.* (2008) estimate increases in public infrastructure costs of 10-20 percent through 2030 and 10% through
45 2080 for Alaska, amounting to several billion dollars, much of it to be spent outside of urban centers. The climate
46 models used were part of the IPCC's coordinated AOGCM model inter-comparison project and the underlying
47 model assumptions are based on a middle-of-the-road "A1B" emissions and growth scenario defined by the IPCC.
48 Lemmen *et al.* (2007) reports that foundation fixes alone in the largely rural Northwest Territories could cost up to
49 CAN\$420 million, and that nearly all of Northern Canada's extensive winter road network, which supplies rural
50 communities and supports extractive industries which bring billions of dollars to the Canadian economy annually, is
51 at risk. Replacing it with all-weather roadways is estimated to cost CAN\$85,000/km.

9.3.4.4. Extreme Weather Events, Sea-Level Rise

The climate change related extreme events that may cause changes in economic values in rural areas include heat waves and droughts, storms, inundation and flooding (Stern 2007; Handmer *et al.*, 2012; Section 3.4.9, Chapter 3, AR5). A detailed discussion on the costs of climate extremes and disasters is set out by Handmer *et al.*, 2012. Costs can be of two kinds: losses or damage costs and costs of adaptation. While some of the costs lend themselves to monetary valuation (such as infrastructure costs) others cannot be easily estimated such as the value of lives lost and the value of eco system services lost (for discussion on the methodologies for valuing costs refer to Handmer *et al.*, 2012; Section 4.5.3).

Damage costs of floods and droughts (Section 10.3.1, chapter 10, AR5) and from rise in water levels in Europe (Swiss Re, 2009a) demonstrate the cost implications for rural communities in the developed regions of the world. Studies mapping the adverse impacts in UK and Europe show a range of sectors that are impacted in rural areas particularly due to drought in Europe and flooding in UK. For instance, major impacts hit farming and forestry with an estimated \$15 billion production lost through drought, heat stress and fire (Munich Re 2004), the worst effect being on summer crops in Mediterranean regions (Giannakoupoulos *et al.*, 2009). Longer term adaptation could reduce the severity of losses but could include displacement of agricultural and forestry production from Southern Europe to the North. The UK Government's Foresight Programme (2004) estimates that global warming of 3 to 4 °C could increase flood damage from 0.1% up to 0.4% of GDP. In Europe costs could rise from \$10 billion today to \$120-150 billion by 2100. With strengthened flood defences these costs may only double. Much of the investment in flood defences and coastal protection would be in rural coastal areas.

Several studies from the developing countries provide evidence on the substantial costs rural communities in particular face in these countries. Salinity and salt water intrusion have implications for rural livelihoods as they impact both fisheries and agriculture (Section 5.5.3, Chapter 5, AR5). Sea level rise also leads to wetland loss and coastal erosion. A few illustrations of the range of impacts of relevance for the rural economy are provided here. Loss of agricultural land and changes in the saline-freshwater interface is estimated to impact the economies of Africa adversely (SEI, 2009, S. Dasgupta *et al.*, 2007). Ahmed *et al.*, (2009) suggest that climate volatility from increase in extreme events, increases poverty in developing countries, particularly Bangladesh, Mexico, Indonesia and in Africa. They also find that on simulating the effect of climate extremes on poverty in Mexico using the SRES A2 scenario as generated by CMIP3 multi-model dataset, rural poverty increases by 43-52% following a single climate shock. Kronik and Verner (2010) note that some 12% of Mexico's population is indigenous and that these rural subsistence communities are vulnerable to extreme weather events and often depend on climate-sensitive crops like coffee. Studying extreme events Boyd and Ibarraán (2009) use a CGE model to simulate the effects of a long drought on the Mexican economy and find declines in production of 10-20% across a variety of agricultural sectors. Scenario-based stakeholder engagement has been tested for coastal management planning under climate change threats (Tompkins *et al.*, 2008) and to determine impacts and responses of extreme-events in coastal areas (Toth and Hizsnyik, 2008).

9.3.4.5. Recreation and Tourism; Forestry

Studies assessing the changes in economic value of recreation and tourism due to climate change are relatively fewer in number (coastal tourism is discussed in Section 5.4.4.2, Chapter 5, AR5). While some studies locate an increase in values for certain regions others estimate shifts in tourism and losses (Bigano *et al.*, 2007; Hamilton *et al.*, 2005; Beniston, 2010), methodological challenges and contrasting findings for the short and long run pose problems in generalizing findings (economic values for recreation and tourism are discussed in Section 10.6, Chapter 10, AR5). Change in economic values will impact rural communities (Lal *et al.*, 2011), with the linkages between biodiversity, tourism and rural livelihoods and rural landscapes being an established one both for developing and developed countries (Nyaupane and Poulde 2011, Scott *et al.*, 2007, Hein *et al.*, 2009).

It has been argued that climate change would have adverse impacts on various ecosystems, including forests and biodiversity in many regions of the world (AR4; Stern, 2007; Eliasch, 2008; Ogawa-Onishi *et al.*, 2010; ADB, 2009a; Tran *et al.*, 2010; Preston *et al.*, 2006) and these will have implications for rural livelihoods and economies

1 (Chopra and Dasgupta, 2008; Safranyik and Wilson, 2006; Kurz *et al.*, 2008; Walton, 2010). However, monetary
2 valuation of changes in non-marketed ecosystem services due to climate change continue to pose a challenge to
3 researchers. To overcome some of the limitations, multicriteria analysis has been used for forest management
4 (Fürstenau *et al.*, 2007).

7 9.3.4.6. Health

8
9 Some studies have looked at the health impacts in various regions of the world, however for the most part these do
10 not by and large distinguish the rural from the urban sector. Studies have examined the linkages between health and
11 climate change in terms of the implications for vector-borne and waterborne diseases for Asia and Africa. No
12 comprehensive assessment of climate change effects on health in Africa or Asia has been conducted so far, and there
13 remain considerable gaps in knowledge (Costello *et al.*, 2009; Byass, 2009). In general it appears that the region of
14 Africa could be seriously affected if counter measures are not put in place (Byass, 2009; Costello *et al.*, 2009; Ebi,
15 2008; SEI, 2009) and that most climate change related health impacts are in children of rural areas in Sub-Saharan
16 Africa and Asia. As there is a lack of studies which consider rural areas specifically, the interested reader is referred
17 to chapter 11 for current sources of vulnerability (Section 11.3.1, Chapter 11, AR5) and major climate sensitive
18 health outcomes (section 11.2, Chapter 11, AR5). A discussion on the additional costs of treatment due to climate
19 related health outcomes is available in Section 10.8.2, chapter 10, AR5. For region specific health concerns from
20 climate change, the reader is referred to the following sections: North America (26.8, chapter 26); Central and South
21 America (27.3.7, chapter 27); Small islands (29.3.3, chapter 29); Australia (25.6.9, Chapter 25); Asia (24.4.6,
22 chapter 24); Europe (23.5.1 and 23.5.2, Chapter 23); Africa (22.3.3.2, chapter 22).

25 9.3.5. Key Vulnerabilities and Risks

27 9.3.5.1. Competing Definitions of Vulnerability

28
29 Discussions on climate vulnerability in rural areas is necessarily related to discussion on competing
30 conceptualizations and terminologies of vulnerability, much of which arises from research based on case-studies
31 located in rural areas. Different conceptualizations are important, because the policy prescriptions for rural areas
32 derived from each are different (O'Brien *et al.*, 2007), or even contradictory. Two main concepts of vulnerability
33 exist (O'Brien *et al.*, 2007; R. Nelson *et al.*, 2010; Füssel, 2007):

- 34 • Vulnerability viewed as a combination of exposure to hazards, sensitivity and adaptive capacity, as used in
35 the Fourth Assessment Report of the IPCC, also called end-point or outcome vulnerability. The resulting
36 policy options derived strongly emphasise new technologies as options to reduce vulnerability and enhance
37 adaptive capacity. One important consequence of this is a downplaying of factors such as gender (V.
38 Nelson *et al.*, 2002) or the status of indigenous people (O'Brien *et al.*, 2009).
- 39 • Vulnerability viewed as arising from pre-existing socio-economic factors that make populations vulnerable
40 to extreme events (or climate change), also called starting-point or contextual vulnerability, emphasizing
41 climate change interactions with multiple processes of change and thus widening the It is assumed that
42 vulnerability arises less from physical sensitivities of the resource base that supports the human system than
43 from the social, economic and political facts that affect how the human system interacts with the resource
44 base. The resulting policy options have a strong focus on diversity and local knowledge (Brondizio and
45 Moran, 2008). This type of assessment has grown in the last few years.

46
47 In line with these interpretations different methodologies exist to measure vulnerability (inductive and deductive
48 methods (Nelson *et al.*, 2010); vulnerability variable, unicriterial or econometric assessment, e.g. centered on
49 examining changes in agricultural yield, and vulnerability indicator or multicriterial approach. Recent discussions in
50 this field also relate to whether studies should be centered on the analysis of vulnerability or resilience. Vulnerability
51 implies a key role for targeted international development assistance in helping the rural poor while resilience
52 research emphasises more bottom-up forms of assistance that allow adaptive capacities and flexible governance
53 structures, and considers that conventional development assistance can exacerbate vulnerability before and after
54 shocks (McSweeney and Coomes, 2011a). Cannon and Muller-Mahn (2010) however, suggest that resilience as a

1 focus is overly associated with the natural sciences while important social issues can be left behind in the
2 assessments.

5 9.3.5.2. Drivers of Vulnerability and Risk

7 In this chapter we use vulnerability as a starting point, in which different trends can be observed in different
8 situations, while we consider risk to be the product of impact, exposure and vulnerability. The most commonly used
9 approaches to analyzing causes of vulnerability, use the concepts of entitlements or livelihoods in evaluating the
10 multi-scale factors shaping people's assets. The importance and impact of drivers affecting vulnerability are seen as
11 context and scale-dependent, although vulnerability is experienced locally, its causes and solutions occur at different
12 social, geographic, and temporal scales (Ribot, 2010). Vulnerability in rural areas can be aggravated by non-climate
13 factors which can operate at both individual and community levels (Eakin and Wehbe, 2009), and include the
14 following:

- 15 • Physical geography, e.g. desert or semi-desert conditions (Lioubimtseva and Henebry, 2009), remoteness
16 (Horton *et al.*, 2010), level of dependence on climate conditions (Brondizio and Moran 2008))
- 17 • Economic constraints and poverty (Ahmed *et al.*, 2011; Macdonald *et al.*, 2009; Mertz, Halsnæs *et al.*,
18 2009; Mertz, Mbow *et al.*, 2009)
- 19 • Gender inequalities (V. Nelson *et al.*, 2002)
- 20 • Social, economic and institutional shocks and trends (e.g. urbanization, industrialization, prevalence of
21 female-headed households, landlessness, short-time policy horizons, low literacy, high share of agriculture
22 in GDP), as well as demographic changes, HIV/AIDS, access and availability of food, density of social
23 networks, memories of past climate variations, knowledge and long-term residence in the region
24 (Macdonald *et al.*, 2009; Mougou *et al.*, 2011; Ruel *et al.*, 2010; Sallu *et al.*, 2010; Simelton *et al.*, 2009;
25 Mertz, Halsnæs *et al.*, 2009; Parks and Roberts, 2006; Gbetibouo *et al.*, 2010; Ahmed *et al.*, 2011; Cooper
26 *et al.*, 2008; Brondizio and Moran, 2008).

28 The adoption of different approaches in the analyses can result in contradictory findings regarding vulnerability in
29 rural areas. Further, vulnerability being highly context-dependent, there are low levels of agreement on the direction
30 in which some key factors may affect vulnerability or resilience in rural areas, including rainfed as opposed to
31 irrigated agriculture, small-scale and family-managed farms, integration into world markets, or poverty. For
32 instance, poverty has traditionally been considered a clear factor increasing vulnerability to climate change, but
33 McSweeney and Coomes (2011a) found that climate-related disasters can change the structural factors, fostering
34 local capacities for endogenous institutional changes that enhance community resilience, intergenerational equity
35 and long-term ecological sustainability. Brouwer *et al.* (2007) contrary to expectations found that vulnerability to
36 flooding in Bangladesh in terms of damage suffered was lower for households that fully depended on natural
37 resources than those who did not fully depend on natural resources. Also Osbahr *et al.* (2008) found that
38 diversification in rural areas does not always reduce vulnerability and can increase inequity within communities if it
39 is not accompanied by reciprocity.

41 There is greater agreement on the importance for resilience of drivers such as access to land and natural resources,
42 flexible local institutions and knowledge and information, and the association of gender inequalities with
43 vulnerability. This section focuses on the following drivers of vulnerability to climate change: water, market
44 orientation, institutions, access to resources, gender, migration and access to information and knowledge.

47 9.3.5.2.1. Access to water

49 Access to drinking and irrigation water is considered an important factor driving vulnerability to climate change of
50 rural populations. Availability of water is also linked to other indicators such as income, agricultural employment
51 and nutritional status in the household (Halsnæs and Trærup, 2009). Reducing vulnerability requires a reduction of
52 the multiple non-climate-related pressures on freshwater resources (e.g. water pollution, high water withdrawals)
53 together with improvement of water supply and sanitation in developing countries (Kundzewicz *et al.*, 2008). It is
54 agreed that water supply will be adversely affected by climate change, but vulnerability of populations will also be

1 determined by other elements, such as the role of institutions in facilitating the access to water, or people's demand,
2 which in turn is influenced by local cultural norms (Wutich *et al.*, 2012) and perceptions of vulnerability which may
3 differ between men and women Larson, Ibes, and White 2011. Improvements in technologies can reduce the
4 perception of water scarcity and increase water demand without reductions in underlying vulnerability (El-Sadek,
5 2010; Sowers *et al.*, 2011). Where appropriate water management institutions exist and are effective, their role in
6 improving rural livelihoods has been demonstrated, for example in Tanzania's Great Ruaha basin (Kashaigili *et al.*,
7 2009).

8
9 Past research has tended to agree that rain-fed agriculture is more vulnerable to climate change (Bellon *et al.*, 2011)
10 and that irrigation is needed to decrease that vulnerability (Gbetibouo *et al.*, 2010). More recent findings suggest that
11 this is context-dependent and irrigation has been found to increase vulnerability in certain cases (Lioubimtseva and
12 Henebry, 2009; Eakin, 2005). Cooper *et al.* (2008) concluded that in rainfed Sub-Saharan Africa the focus should be
13 on improving productivity of rain-fed agriculture instead of irrigation as irrigation schemes are also being threatened
14 by drought, and Ahmed *et al.* (2011) emphasised the role of drought-tolerant crops. It is important, both for rain-fed
15 and irrigated agriculture, to promote water harvesting strategies, including storage and conservation.

16 17 18 9.3.5.2.2. *Market orientation*

19
20 Some authors argue that opening markets to international trade increases vulnerability of small farmers and poor
21 people. However, linkages among international, regional and local markets are not clear, including how global
22 prices affect regional and local prices in the long term (Ulimwengu *et al.*, 2009). Market integration reduces the
23 capacity of indigenous systems for dealing with climate risk in Bolivia (Valdivia *et al.*, 2010) and Mozambique
24 (Eriksen and Silva, 2009), and in the Sahel favours a shift towards cash-cropping a narrow range of commodities
25 that increased dryland degradation (Fraser *et al.*, 2011) as in Honduras (McSweeney and Coomes, 2011a), by
26 accelerating socioeconomic stratification or focusing incomes in a single crop. Ruel *et al.* (2010) suggest that
27 excessive dependence on cash income increases vulnerability of the urban poor compared with the rural poor, who
28 can have access to other type of assets. According to Brooks *et al.* (2009) the dominant development paradigm
29 favouring transitions from tradition to modernization, economic growth and globalization, does not favour action
30 under uncertainty. They suggest the need for new models of development built *around* environmental constraints
31 and opportunities which search for a balance between productivity and resilience.

32
33 On the other hand, Jones and Thornton (2009) estimated that rainfed mixed crop/livestock areas in sub-Saharan
34 Africa which are far from large markets have higher poverty rates and thus, conclude they are more vulnerable to
35 climate change. Also Gbetibouo *et al.* (2010) proposed increased market participation as a valid measure to reduce
36 vulnerability of vulnerable regions in South Africa as calculated by a vulnerability index. Thus, each case needs to
37 be analysed within its complexity considering interactions among all factors that can affect vulnerability, to avoid
38 magic recipes which can work in one place but not in other (Rivera-Ferre *et al.*, submitted).

39
40 Regarding the scale of farms, some authors suggest that high reliance on small-scale farming increases the
41 vulnerability of communities in rural areas (Bellon *et al.*, 2011; Gbetibouo *et al.*, 2010) although it is suggested that
42 their resilience capacity (stemming from factors such as indigenous knowledge, family labour, livelihood
43 diversification) should not be underestimated. On the contrary, Brondizio and Moran (2008) indicate that small
44 farmers are less vulnerable than large, monocrop farmers when climatic variations make an area inappropriate for a
45 particular crop, because they tend to cultivate multiple crops. However, they recognize that small farmers tend to
46 suffer from technological limitations, low access to extension services, and market disadvantages. Mertz *et al.*
47 (2009) suggest that history demonstrates small farmers are highly resilient as they face numerous changes and that
48 the value of local knowledge in climate change studies has received little attention. For Eakin (2005), the shift in
49 support to agriculture from subsistence to commercial agriculture in Mexico reduced smallholders resilience for
50 climatic variations.

9.3.5.2.3. *Institutions, access to resources, and governance*

Vulnerability and livelihood security are closely linked to the institutional environment. Institutions and their networks can increase (Eakin, 2005) or reduce vulnerability to climate change. For that reason it is important to foster research on the role of local institutions in influencing vulnerability (Agrawal and Perrin 2008; Berman *et al.*, 2012). According to Agrawal and Perrin (2008) local institutions (as organizations) influence livelihoods in three manners: through distribution of risks related to climate hazards they can structure how particular social groups will be affected by them; they determine the incentive structures for household and community level adaptation responses; and they mediate external interventions (e.g. finances, knowledge and information, skills training) into local contexts, and articulate between local and extra-local social and political processes through which adaptation efforts unfold. In that manner, rural institutions structure risk and sensitivity in the face of climate hazards by enabling or disabling individual and collective action (Ribot, 2010). Governance structures and communication flows are important, as shown in a Swiss mountain region vulnerable to climate change (Ingold *et al.*, 2010). The knowledge and perceptions of decision-makers are important. Romsdahl *et al.* (2013) show that local government decision-makers in the US Great Plains resist seeing climate change as within their responsibilities, which has contributed to low levels of planning for either adaptation or mitigation, and thus to greater vulnerability, but that a reframing of issues around current resource management priorities could allow proactive planning.

According to Leach *et al.* (1999) institutions (as the rules of the game in society) mediate vulnerability by shaping access to resources as composed by endowments, entitlements and capabilities of different social actors. Anderson *et al.* (2010) associate flexible local institutions in dryland societies, primarily for resource management, with resilience to climate change and vulnerability reduction. Lack of access to assets, among which land is an important one, is accepted to be an important factor increasing vulnerability in rural people (McSweeney and Coomes, 2011a). The breakdown of traditional land tenure systems increases vulnerability (Fraser *et al.*, 2011; Dougill *et al.*, 2010) in many different ways. Lack of access to land is a multi-causal process, among which climatic change is just but one. For instance, Dougill *et al.* (2010) shows that land privatization in Botswana has increased vulnerability of poorer communal pastoralist, although it has helped the wealthier farmers, remaining a route to enhance resilience as this private land-owning group has become less vulnerable. Brouwer *et al.* (2007) found that individuals with less access to natural productive resources are more vulnerable to flooding, being even higher when disparities of distribution at the community level are also higher. Lack of access to productive land is also linked to migration and conflicts. Obioha (2008) shows how reduction of access to productive land due to climatic changes increases communal civil violent conflicts in Nigeria.

9.3.5.2.4. *Migration*

The relationship of vulnerability to migration is complex. Vulnerable people can migrate, both as a coping and as an adaptive strategy, depending on the temporal scale of that migration. Areas of out-migration can experience reduced vulnerability if migrants send remittances, or increased vulnerability if the burden of work, usually for women, also increases. Social networks, essential to reduce vulnerability, are also affected reducing the transmission of traditional knowledge (Valdivia *et al.*, 2010). Furthermore, those places receiving migrants can experience an excessive demographic growth, which increases pressure over scarce resources, as it is being experienced in the semiarid tropics (Cooper *et al.*, 2008) or Africa (Obioha, 2008). Brondizio and Moran (2008) found that in-migration in the Amazon brought people with knowledge that is ill-adapted to the local environment.

9.3.5.2.5. *Gender*

Gender was a “latecomer” to the climate debate (Denton, 2004), but patterns of vulnerability reflects gender-related inequalities, of special relevance to rural areas in the developing world (Denton, 2002; Vincent *et al.*, 2010; V. Nelson and Stathers, 2009). Gender differences in roles, responsibilities and capabilities mean that climate change may actually reinforce disparities between men and women (Vincent *et al.*, 2010), in crucial key dimensions for coping with climate-related change, including inequalities in access to wealth, new technologies, education,

1 information, and other resources such as land. The major issues concerning gender and climate change in rural areas,
2 not only in terms of vulnerability but also of enabling adaptation, are reviewed in Box 9-2.

3
4 _____ START BOX 9-2 HERE _____

6 **Box 9-2. Gender and Climate Change in Rural Areas**

7
8 Differences in access to resources between men and women can create gender inequalities, which in turn leads to
9 differential vulnerabilities and capacities to adapt (Nelson *et al.*, 2002; Adger, 2006; O'Brien *et al.*, 2007). Whilst
10 recognised in AR4 (Adger *et al.*, 2007) and SREX (IPCC, 2012), evidence since then has become stronger, with
11 additional case studies on the gendered dimensions of climate change (e.g. Nelson and Stathers, 2009; Vincent *et al.*,
12 2010). The social constructions of gender roles and responsibilities mean that women are typically disadvantaged
13 relative to men. Due to greater levels of out-migration by men, women are disproportionately represented in rural
14 areas, and globally women in rural areas make up one quarter of global population (Inter-Agency Task Force on
15 Rural Women, 2012). As a result, it is essential that a chapter on rural areas be gender-sensitive. This box
16 summarises the gender elements of vulnerability, impacts, and adaptation in rural areas.

17
18 Gendered differences exist in experiences of the multiple stresses that affect rural areas. Access to land shows strong
19 differences between men and women, as do labour markets (FAO, 2010) and access to non-farm entrepreneurship
20 (Rijkers and Costa, 2012). Less than 20% of the world's landholders are women, but women still play a
21 disproportionate role in agriculture. On average women make up around 43% of the agricultural labour force in
22 developing countries; in South Asia almost 70% of employed women work in agriculture, and more than 60% in
23 sub-Saharan Africa (Inter-Agency Task Force on Rural Women, 2012). Climate change increases vulnerability
24 through male out-migration that increases the work to women; cropping and livestock changes that affect gender
25 division of labour; increased difficulty in accessing resources (fuelwood and water) and increased conflicts over
26 natural resources. These factors can make rural women more vulnerable than men, in terms of reductions in
27 resources, potential loss of employment and raised food prices (e.g. Tandon, 2007; Rossi and Lambrou, 2008; Ruel
28 *et al.*, 2009). Evidence for gendered vulnerability to climate change in rural areas exists in Africa (e.g. Omolo, 2011;
29 Huisman, 2005).

30
31 In addition to differential access to resources and property rights, gender-ascribed social roles and responsibilities
32 can also mean that women are differentially affected by climate extremes. Women are generally more vulnerable to
33 the impacts of extreme events, such as floods and tropical cyclones. This occurs due to a combination of being close
34 to the homestead, not having access to information (such as early warnings), and lacking the skills to survive, such
35 as swimming. As well as differential immediate effects of extreme events, women are typically disadvantaged
36 relative to men in the relief and recovery period (Alam and Collins, 2010). Lack of gender-sensitivity in emergency
37 camps (e.g. different sanitation facilities) can put women's personal security at risk; and as social constructions of
38 gender determine that they should be responsible for taking care of other household members; although there have
39 been calls to add nuances to these differences (Cupples, 2007). Although there is little agreement in the role of
40 environmental migration in response to climate change, women are disadvantaged in accessing this option
41 (Foresight: Migration and Global Environmental Change, 2011).

42
43 Enabling adaptation of men and women requires a gender-sensitive approach that recognises and addresses the
44 differential vulnerabilities. Not taking a gender-sensitive perspective can risk reinforcing existing vulnerabilities
45 (Figueiredo and Perkins, 2012; Arora-Jonsson, 2011). However it is also important to move beyond generic gender
46 differences and examine gender alongside other factors (Tschakert, 2013). Government interventions to improve
47 production through cash-cropping and non-farm enterprises, for example, typically advantage men over women
48 since cash income is seen as a male activity in rural areas (Gladwin *et al.*, 2001); whilst rainwater and conservation-
49 based adaptation initiatives may require additional labour which women do not necessarily have (Baiphethi *et al.*,
50 2008). Encouraging gender-equitable access to education and strengthening of social capital are among the best
51 means of improving adaptation of rural women farmers (Below *et al.*, 2012; Goulden *et al.*, 2009; Vincent *et al.*,
52 2010). Similarly recognising preferences in accessing adaptation-enabling information is important: in South Africa,
53 for example, it was observed that women preferred to hear seasonal forecasts through extension agents, as opposed

1 to over the radio like men (Archer, 2003); whilst in Ghana information is broadcast over the radio, but women only
2 hear it if they happen to be in the company of men who are listening (Nab and Korenteng, 2012).

3
4 _____ END BOX 9-2 HERE _____

7 9.3.5.2.6. *Knowledge and information*

8
9 Knowledge and information debates are very much linked to institutions, since knowledge is in itself a component
10 of institutions. Lack of access to information and knowledge of rural people is suggested as a factor that increases
11 vulnerability, mostly among poor people, which can also affect the above mentioned drivers. What is not so much
12 agreed in the literature is what type of knowledge is best to reduce vulnerability. Some authors suggest the need for
13 local responses and indigenous knowledge to reduce vulnerability (Valdivia *et al.*, 2010), and call for an integration
14 of local knowledge into climate policies (Nyong *et al.*, 2007), while Bellon *et al.*, (2011) state that local knowledge
15 and traditional institutions are too local, and in some contexts gathering information from further away is important.
16 They find that to face the forecasted climatic changes, the geographical area of exchange of seeds should be larger
17 than the one covered by the traditional systems of seed exchange.

18
19 Access to information is also important, shared knowledge and lessons learned from previous climatic stresses
20 provide vital entry points for social learning and enhanced adaptive capacity (Tschakert, 2007). However, access to
21 information is not always a guarantee of success. Coles and Scott (2009) found that in Arizona, despite ample access
22 to weather forecasting, ranchers did not rely on such information, implying that changes are required to make more
23 attractive information to users, as well as to understand prevailing local cultures and norms.

24
25 It is also important in the debate how knowledge is produced, managed, and disseminated within the formal
26 institutional structure to address vulnerability issues. A local case-study in Sweden shows that limited co-operation
27 between local sector organisations, lack of local co-ordination, and an absence of methods and traditions to build
28 institutional knowledge exist, posing barriers to manage vulnerability (Glaas *et al.*, 2010). To address this it is
29 suggested that local institutional structure must be flexible and encourage institutional learning and knowledge
30 transfer, implementing communication mechanisms between public authorities, other knowledge producers, and
31 civil society to favour more reliable assessments of local vulnerabilities (Glaas *et al.*, 2010). Moumouni and Idrissou
32 (2013 and forthcoming) examine the lack of co-ordination in Benin between climate policies and the policies and
33 practices which govern agricultural research and extension, while good practice at project level could be harnessed
34 to foster collective learning of farmers and other agricultural stakeholders, and thus adaptation to climate change.

35
36 The importance of access to knowledge and information has also been addressed with other drivers, suggesting that
37 the combined pressure of climate change-induced decreased access to resources, the institutional vacuum, the loss
38 of esteem for authorities, and the loss of trust in cultural knowledge accentuates the need to address governance to
39 improve access to resources, access to information, mutual understanding of the role of knowledge systems for the
40 interpretation of climate change and variability, and relevant institutional capacities (Kronik and Verner, 2010). In
41 this direction, an alternative mode of interaction to the science and practice one-way interaction often used to
42 address vulnerability, adaptation and resilience, in which different experts, risk-bearers, and local communities are
43 involved and knowledge and practice is contested, co-produced and reflected upon it (Vogel *et al.*, 2007).

46 9.3.5.3. *Outcomes*

47
48 The outcome of vulnerability is the result of and interaction of the driving forces that determine vulnerability. This
49 section analyses how different drivers may affect specific vulnerable groups in rural areas, that is pastoralists,
50 mountain farmers and artisanal fisherfolk. Box 9-3 takes a specific economic sector important in rural areas, and
51 demonstrates the interplay of vulnerability and exposure.

1 _____ START BOX 9-3 HERE _____

3 **Box 9-3. Tourism and Rural Areas**

4
5 The three major market segments of tourism most likely to be affected by climate change are rural-based, namely,
6 coastal tourism, nature-based tourism and winter sports tourism) (Scott *et al.*, 2012). Tourism is a significant rural
7 landuse in many parts of the world, yet compared to other economic sectors in rural areas, the impacts of climate
8 change are typically under-researched. In the Caribbean, for example, tourism has overtaken agriculture in terms of
9 economic importance, with several regional states (including the Bahamas, the Cayman Islands and St Lucia)
10 receiving more than 60 percent of their GDP from this industry (Meyer, 2006). Coastal environments elsewhere in
11 the world are also characterised by dependence on rural tourism, and are known to be vulnerable to cyclones and sea
12 level rise (Klint *et al.*, 2011; Payet, 2007).

13
14 Terrestrial natural resource-based tourism is also a significant foreign exchange earner in many countries. In sub-
15 Saharan Africa, between 25 and 40% of mammal species in national parks are likely to become endangered by 2080,
16 assuming no species migration (and 10-20% with the opportunity for migration) (Thuiller *et al.*, 2006). There are
17 also many rural environments viewed as “iconic” or having cultural significance that are vulnerable to climate
18 change. In South Africa, for example, the Cape Floral (fynbos) ecosystem has a high level of species endemism
19 which will be vulnerable to the projected increase in dry conditions (Midgley *et al.*, 2002; Boko *et al.*, 2007). The
20 projected increase in climate change-related hazards, such as glacial lake outbursts, landslides, debris flows and
21 floods, will likely affect trekking in the Nepali Himalayas (Nyaupune and Chhetri, 2009).

22
23 The development of tourism has, in many cases, increased levels of exposure to climate change impacts. In the
24 Caribbean, for example, tourism has led to considerable coastal development in the region (Potter, 2000), which
25 may exacerbate vulnerability to sea-level rise. In many cases, the carbon emissions resulting from participating in
26 rural tourism threaten the very survival of the areas being visited. This is often the case for very remote locations,
27 for example polar bear tourism in Canada (Dawson *et al.*, 2010), dive tourism in Vanuatu (Klint *et al.*, 2012).
28 Although on aggregate resource consumption of tourists and locals has been shown to be similar in developed
29 county contexts (e.g. in Italy – Patterson *et al.*, 2007); in many developing countries resources used by tourists are
30 much higher than locals (e.g. in Nepal - Nepal, 2008).

31
32 Despite the potential impacts of climate change on rural tourism, there is little evidence of significant concern,
33 which impedes adaptive responses. Surveys in both the upper Norrland area of northern Sweden and New Zealand
34 showed that climate change is not perceived to pose a major threat in the short term, relative to other business risks
35 perceived by small business owners and tourism operators (Broudera and Landmarka, 2011; Hall, 2006).

36
37 That said, there is evidence that, with planned adaptation, tourism can flourish in rural areas under climate change.
38 In the Costa Brava region of Spain, for example, although the increasing temperatures and reduced water availability
39 is projected to negatively impact tourism in the current high seasons, there is scope to shift to the current shoulder
40 seasons, namely April, May, September and October (Ribas *et al.*, 2010). Recognition of the opportunities for
41 adaptation have also necessitated reassessment of the extent of the potential impacts of climate change on the
42 tourism industry in rural areas. Using snowmaking as an adaptation in the eastern North American ski industry
43 suggests that even the warmest scenario only poses a minor risk to four out of six areas (Scott *et al.*, 2006).

44
45 _____ END BOX 9-3 HERE _____

48 9.3.5.3.1. *Pastoralists*

49
50 Pastoralists have developed successful strategies for responding to climate variability, especially what Krätli *et al.*
51 (2013) refer to as “strategic mobility” in pursuit of high-quality grazing, in combination with shorter-term coping
52 strategies (Morton, 2006), for example in the Afar region of Ethiopia (Davies and Bennett, 2007). These strategies
53 suggest that a strong adaptive capacity is intrinsic to pastoralism (Davies and Nori, 2008). However, traditional
54 practices such as pastoral mobility are declining, which increases the vulnerability of people in arid and semiarid

1 regions (Lioubimtseva and Henebry, 2009; Fraser *et al.*, 2011). Drought may become famine because of
2 privatization policies that limit pastoral mobility making pastoralists dependent on rainfed agriculture (Smucker and
3 Wisner 2008). Furthermore, the lack of other alternatives in certain marginal areas where animals are the only secure
4 assets can lead to overstocking and overgrazing, and thus, to increased vulnerability of pastoralism (Cooper *et al.*,
5 2008).

6
7 These constraints arise from a range of social, economic, environmental and political pressures external to
8 pastoralism that bring about “induced vulnerability” (Krätli *et al.*, 2013): especially encroachment on rangelands,
9 inappropriate land policy, undermining of pastoral culture and values, and economic policies promoting uniformity
10 and competition over diversity and complementarity. Other authors list as constituents of increased vulnerability:
11 population growth; increased conflict over natural resources; changed market conditions and access to services
12 under liberalisation; concentration of political power in national centres; and perceptions that pastoralists are
13 backward (Dougill *et al.*, Fraser, and Reed, 2010; Rivera-Ferre and López-i-Gelats, 2012; Smucker and Wisner,
14 2008; Dong *et al.*, 2011). These in turn can be seen as results of what Reynolds *et al.*, (2007) conceptualise as two
15 key features of dryland populations: remoteness, and distance from the centres and priorities of decision-makers or
16 “distant voice”. However Dong *et al.* (2011) and Sietz *et al.* (2011) stress the geographic differentiation of pastoral
17 systems (and more broadly of dryland systems with which they overlap).

18 19 20 9.3.5.3.2. *Mountain farmers*

21
22 Mountain ecosystems have been identified as extremely vulnerable to climate change (IPCC 2007), and thus
23 populations have a high exposure to climate change. A detailed understanding of climate change impacts in
24 mountain areas is difficult because of physical inaccessibility and scarcity of resources for research in mountain
25 states and regions (Singh *et al.*, 2011), as well as more generic uncertainties relating to climate projection. However,
26 agreement exists that impacts will include melting of glaciers, flooding or increasing probability of fires (Nogués-
27 Bravo *et al.*, 2007; Beniston, 2003). This will in turn have strong impacts on agriculture and livestock-based
28 activities in these areas (e.g., changes in plants, pastures and water availability; slope instability; new diseases) as
29 well as on tourism-based activities (Scott, 2006). But mountain dwellers, as pastoralists in drylands, are adapted to
30 live in steep and harsh and variable conditions, and thus have a variety of strategies to adapt and foster resilience to
31 changing climatic conditions. However, to develop their strategies they need to overcome other drivers that can
32 affect their vulnerability in different contexts. For instance, in most developed countries, mountains are becoming
33 depopulated (Gellrich *et al.*, 2007; López-i-Gelats, 2013; Gehrig-Fasel *et al.*, 2007) given the extreme climatic
34 conditions, their remoteness and subsequent isolation, while in developing countries there is a trend towards
35 increasing population (e.g. tropical mountain areas) (Lama and Devkota, 2009; Huber *et al.*, 2005). The impacts of
36 the projected warming on mountain farming, as well as their adaptation strategies, differ spatially because the
37 socioeconomic role of mountains varies significantly between industrialized and industrializing or non-industrialized
38 countries (Nogués-Bravo *et al.*, 2007). Mountain grasslands in developed countries are usually managed via a sub-
39 exploitation model that involves the intensive use of the most productive areas and the abandonment of those
40 regions where production is economically less viable (López-i-Gelats *et al.*, 2011). In contrast, mountain grasslands
41 in developing countries remain centers of fodder and livestock production. Thus, two general trends are identified in
42 world mountain grasslands, while temperate grasslands tend to suffer from conversion to agriculture, and land
43 abandonment where livestock raising is less feasible (Gellrich *et al.*, 2008); in tropical grasslands the main cause of
44 degradation is overgrazing, linked to processes of demographic growth. Land privatization, loss of grazing rights, or
45 changes in land use (e.g., development of infrastructure) also affect mountain farmers both in developed and
46 developing countries (Tyler *et al.*, 2007; Xu *et al.*, 2008).

47 48 49 9.3.5.3.3. *Artisanal fisherfolk*

50
51 Small coastal and riparian rural communities face several drivers that increase their vulnerability, which remain
52 largely ignored by mainstream fisheries policy analysts; for example, the likely impact of demographic, health and
53 disease trends, or of wider development policy trends (Hall, 2011), pressure from other resources (e.g. water,
54 agriculture, coastal defense), unbalanced property-rights; lack of adequate health systems, potable water, or sewage

1 and drainage (Badjeck *et al.*, 2010). The most important drivers affecting small-scale fisheries can be grouped into:
2 international trade and globalization of markets; technology; climate and environment; health and disease;
3 demography; development patterns and aquaculture; for instance, freshwater fisheries are threatened by increasing
4 irrigation, while vulnerability of coastal fisheries increases with mangrove loss to aquaculture facilities in response
5 to growing markets for prawns (Hall, 2011). Another difficulty faced by fisheries-based livelihoods is the neglect of
6 governments and researchers, which is more centred on industrial fishing leaving aside artisanal ones (Mills *et al.*,
7 2011). Management systems, property rights and institutions are extremely important in fisheries. Given the
8 complexity of fisheries management and the particular open ecosystem in which this activity is carried out, the
9 existing discussions about fisheries management are complex but also advanced in terms of introducing ecosystem
10 rights and participation principles into management (Andrew and Evans, 2011; Charles, 2011), which in other fields
11 are essential for reducing vulnerability, adapting to climate change and favouring sustainable societies.
12
13

14 **9.4. Adaptation and Managing Risks**

15 **9.4.1. Framing Adaptation**

16
17
18 As the previous sections outlined, it is virtually certain that there will be impacts of climate change in rural areas in
19 both developed and developing countries for which adaptation is required. AR4 stated with very high confidence
20 that adaptation to climate change is already taking place, but on a limited basis. Since then, evidence has increased
21 such that there is very high confidence that adaptation is taking place in rural areas. Many adaptations build on
22 examples of responses to past variability in resource availability, and it has been suggested that the ability to cope
23 with current climate variability is a prerequisite for adapting to future change (Cooper *et al.*, 2008). At the same
24 time, however, it cannot be assumed that past response strategies will be sufficient to deal with the range of
25 projected climate change. In some cases, existing coping strategies may increase vulnerability to future climate
26 change, by prioritising short-term resource availability (O'Brien *et al.*, 2008; Adepetu and Berthe, 2007). In
27 developing countries, there is high confidence that adaptation could be linked to other development initiatives
28 aiming for poverty reduction or improvement of rural areas (Nielsen *et al.*, 2012; Hassan, 2010; Eriksen and
29 O'Brien, 2007). In Ethiopia, for example, “low regrets” measures to respond to current variability are important to
30 shift the trajectory from disaster-focused to longer-term vulnerability reduction (Conway and Schipper, 2011).
31
32

33 **9.4.2. Decisionmaking for Adaptation**

34
35 Decision-making for adaptation takes place at a variety of levels, and can be public or private. At the national and
36 local levels, law and policies can enable planned adaptation (Stuart-Hill and Schulze, 2010). Evidence for policies to
37 support adaptation exists from across the world, but tends to be greater in developed countries. In Australia, the
38 Queensland government has set policies in anticipation of sea level rise, and in New Zealand the revised Coastal
39 Policy Statement requires a minimum 100-year time frame for coastal planning (see Box 25-2). Australia also has a
40 comprehensive water resources policy designed to deal with scarcity (see Box 25-3). In northern Canada, some
41 territorial governments in Northern Canada have developed climate change strategies that promote further
42 adaptation such as providing hunter support programs (Ford *et al.*, 2010)(see also chapter 26). However, in the
43 Great Plains of the US, less than 20% of jurisdictions have developed plans on either climate adaptation or climate
44 mitigation (Romsdahl *et al.*, 2013).
45

46 At the local level, many adaptations are examples of private decisions for adaptation. As shown with very high
47 confidence in AR4, such adaptation decisions are embedded in the inter-relationship of a variety of social factors in
48 which climate drivers are only one consideration (Crane *et al.*, 2011). An example of where public policy can
49 support private adaptation is in index-based insurance schemes. In Africa where understanding of insurance is low,
50 participation rates can be improved by using simulation games, as trialed in Ethiopia and Malawi, or by more
51 conventional training methods (Patt *et al.*, 2010). Data from India, Africa and South America shows that the trust
52 that people have in the insurance product and the organisations involved in selling and managing it may be more
53 important than economic factors, such as the size and timing of the premium and potential payouts (Patt *et al.*,
54 2009). However, private decisions often take place in the context of national policies and laws, which are not always

1 mutually-supportive (Stringer *et al.*, 2009), especially in the agropastoral sector where settlement is encouraged
2 (Awuor *et al.*, 2011).

3
4 One major difference between public and private decision-making is that that latter is typically more responsive. An
5 analysis of agricultural water schemes in South America, for example, found that private irrigation schemes increase
6 in response to a warmer climate, whereas public ones do not, and that they are taken gradually (Seo, 2011b).

7 Participatory stakeholder processes to inform public policy and law can take time. A case study of a resettlement
8 programme in Mozambique showed that farmers and policymakers disagreed about the seriousness of the climate
9 risks, and the potential negative consequences of proposed adaptive measures (Patt and Schroeter, 2008). In
10 Bangladesh, the ambitious national Flood Action Plan (FAP) did not receive support from NGOs, who embarked
11 upon an anti-FAP movement and attained what they perceived to be a more people-oriented national water policy
12 (Mallick *et al.*, 2005).

13
14 There is increasing evidence that public decision-making for adaptation can be strengthened by understanding the
15 decision-making of rural people in context (Bryan *et al.*, 2009). Local and indigenous knowledge for responding to
16 weather events and a changing climate has been observed in, for example, the Peruvian Andes (see chapter 26),
17 Samoa (Lefale, 2010 – see chapter 29), the Solomon Islands (Rasmussen *et al.*, 2009 – see chapter 29), Canada (Ford
18 *et al.*, 2007) and the Indo-Gangetic Plains (Rivera-Ferre *et al.*, 2013).

21 **9.4.3. Practical Experiences of Adaptation in Rural Areas**

22
23 There are wide-ranging and manifold examples of adaptation in rural areas, in both developed and developing
24 countries. These practical experiences of adaptation are found in agriculture, water, forestry and biodiversity, and
25 fisheries.

28 **9.4.3.1. Agriculture**

29
30 Agricultural societies have a history of responding to the impacts of change in exogenous factors, including (but not
31 limited to) weather and climate (Mertz *et al.*, 2009). They undertake a range of adjustment measures relating to their
32 farming practices – for example, planting, harvesting and watering/fertilizing existing crops; using different
33 varieties, diversifying crops; implementing management practices such as shading and conservation agriculture (see
34 Table 9-6).

35
36 [INSERT TABLE 9-6 HERE

37 Table 9-6: Examples of adaptations in the agricultural sector in different regions.]

38
39 Conservation agriculture shows promising results and can be used as an adaptation (Nyala *et al.*, 2011) and for
40 sustainable intensification of production (Pretty *et al.*, 2011), with significant yield productions observed in South
41 Asia and southern Africa (Erenstein *et al.*, 2012). In other cases, the potential effectiveness of adaptation under
42 future climate scenarios has been modeled, for example in Cameroon (Tingem and Rivington, 2009), and for the
43 African continent (Seo, 2011a). Water management for agriculture is also critical in rural areas under climate
44 change, for example the use of rainwater harvesting (Biacin *et al.*, 2011; Kahinda *et al.*, 2010, Vohland and Barry,
45 2009; Rivera-Ferre *et al.*, 2013), and more efficient irrigation, particularly in rural drylands (Thomas, 2008).

46
47 Adaptations are also evident among small-scale livestock farmers (Rivera-Ferre and López-i-Gelats, 2012; Kabubo-
48 Mariara, 2009, 2008), who use many different strategies, including changing herd size and composition, grazing and
49 feeding patterns, or diversifying their livelihoods, also they may use new varieties of fodder crops suited to the
50 changing conditions (Salema *et al.*, 2010).

51
52 Diversified farms are more resilient than specialized ones (Seo, 2010); but rural societies also diversify their income
53 sources beyond agriculture, which in many contexts allows them to reduce their risk exposure. Examples include the
54 exploitation of gums and resins in Kenya (Gachathi and Eriksen, 2011). There may be some rural areas, however,

1 where limits to agricultural adaptation are reached, and thus the only option that remains is to migrate or diversify
2 away from farming (Mertz *et al.*, 2011).

3 4 5 9.4.3.2. *Water* 6

7 As well as being an important input to agriculture, adaptation in water resources in general is critical in rural areas.
8 Given projected reductions in water availability, improved management is required. The extent to which such
9 adaptation measures have been implemented to date varies: in a study from Europe, Africa and Asia, the Elbe and
10 Rhine basins had the highest level of water resource management measures in place, followed by the Orange and
11 Guadiana, with lower levels in the Amu Darya and Nile Equatorial Lakes (Krysanova *et al.*, 2010). In the Middle
12 East and North Africa, whilst supply-side measures are advanced, little attention has been paid to the demand-side
13 measures that will be critical in a changing climate (Sowers *et al.*, 2010). In the cases of transboundary basins
14 additional barriers exist to adaptive management measures, particularly in Africa (Goulden *et al.*, 2009a), although
15 examination of potential institutional designs has been undertaken (Huntjens *et al.*, 2012). The need for effective
16 water management for adaptation therefore exists not only at the basin level, but at a higher resolution, for example
17 in human settlements and towns (Mukheibir, 2008).

18
19 Whilst the majority of focus on adaptation concerning water relates to its availability, it is also important to
20 remember that many rural areas are subject to riverine or coastal flooding. In the low-lying Netherlands protection
21 measures have been employed, including increasing river runoff, increasing storage for water (Delta Committee,
22 2008; Kabat *et al.*, 2009), and small scale containment of flood risks through increasing compartmentalisation (Klijn
23 *et al.*, 2009). In the Mekong Delta in Vietnam, Columbia University’s Center for International Earth Science
24 Information Network has projected that a “one-meter sea-level rise could result in the displacement of more than
25 seven million residents in the delta, and a two-meter rise would double to 14 million- or 50 percent of the delta
26 residents.” An increase in flood frequency and magnitude has threatened residents’ lives and created instability in
27 crop fields. As rapid industrialization has placed stresses on the environment and Vietnam’s natural resources, many
28 people in Mekong have adapted by moving east to cities with rapid economic growth. The government’s “living
29 with floods” program has encouraged rice farmers to shift to aquaculture, while the planned relocation of 20,000
30 “landless and poor households” has altered social networks and livelihoods (De Sherbinin *et al.*, 2011).

31
32 [INSERT TABLE 9-7 HERE

33 Table 9-7: Examples of adaptations in the water sector observed in different regions.]
34
35

36 9.4.3.3. *Forestry and Biodiversity* 37

38 Effective management is also essential for adaptation of forests and biodiversity to climate change. As with water
39 resources, forests can adapt through management of forest fires, silvicultural practices, and the conservation of
40 forest genetic resources. Ecological restoration, where required, is another effective adaptation measure – Benayas *et al.*
41 (2009), in a meta-analysis of 89 studies, estimated this technique enhances the provision of biodiversity and
42 environmental services by 44% and 25%, respectively. Moreover, ecological restoration increases the potential for
43 carbon sequestration and promotes community organization, economic activities and livelihoods in rural areas
44 (Chazdon, 2008), as seen in examples of the Brazilian Atlantic Forest (Calmon *et al.*, 2011; Rodrigues *et al.*, 2011).
45 In other parts of Africa, the systematic analysis of current policies and practices in order to understand the nature
46 and extent of intervention required is often lacking (Fobissie *et al.*, 2009).

47
48 Forest resources have been shown to play a role in enabling adaptation during extreme events in Zambia, Mali and
49 Tanzania, although should take place within a managed context to ensure sustainability (Robledo *et al.*, 2011). As
50 the climate changes, part of adaptive management may entail modification of existing biodiversity management
51 practices. In addition to land and water management and law and policy, direct species management is important
52 (Mawdsley *et al.*, 2009). In terms of managing protected areas, to maintain appropriate habitats a network approach
53 may be effective (Hole *et al.*, 2011).
54

1 Community involvement in natural resources management and biodiversity conservation is highlighted as critical,
2 with community-managed natural areas experiencing lower rates of deforestation than non-community-managed
3 ones (Porter-Bolland et al, 2012). In Central and South America, protected areas of restricted use reduced fire
4 substantially, but multi-use protected areas are even more effective; and that in indigenous reserves the incidence of
5 forest fire was reduced by 16% as compared to non-protected areas (Nelson and Chomitz, 2011). Reflecting the
6 growing evidence for community-based management and wise use, an emerging mechanism for ecosystem-based
7 adaptation includes payment for ecosystem services (PES) (Montagnini and Finney, 2011), although there is
8 virtually no peer-reviewed literature on PES specifically for emissions reduction (Campbell, 2009). Particularly
9 developed in Central and South America (see table 27-5 for examples of PES schemes in Latin America),
10 communities can be paid for collecting scientific data to contribute to research and monitoring protocols (Luzar *et*
11 *al.*, 2011), or for actively managing natural resources.

14 9.4.3.4. Fisheries

16 Adaptation in marine ecosystems is also of relevance to rural areas. Bleaching of coral reefs through rising
17 temperatures causes habitat loss which, in turn, affects fisheries. Selective use of fishing gear is a recommended
18 management measure, based on 15 global sites, to ensure sustainable harvesting of remaining fish stocks (Cinner *et*
19 *al.*, 2009). As with other ecosystems, the extent to which adaptation is required will depend on existing capacity. Of
20 5 countries in the southwestern Indian Ocean, the environmental sensitivity in Mauritius is offset by the higher
21 adaptive capacity (based on a multi-faceted social adaptive capacity index they used in the study), although the more
22 environmentally-sensitive parts of Madagascar will be priorities for intervention assistance (McClanahan *et al.*,
23 2009). As with terrestrial natural resources, evidence from the marine resources sphere shows that fisheries co-
24 management, involving local fishermen and allowing limited extraction of resources, favour a balance between
25 resource conservation and livelihoods, e.g in Brazil (Francini-Filho and Moura, 2008), and the improvement of
26 livelihoods, as well as the cultural survival of traditional populations (Hastings, 2011; Moura *et al.*, 2009). Given the
27 complexity of fisheries management and the particular open ecosystem in which this activity is carried out, the
28 existing discussions about fisheries (adaptive) management are complex but also advanced in terms of introducing
29 ecosystem, rights and participation principles into management (Andrew and Evans 2011; Charles 2011), which are
30 essential to reduce vulnerability and adapt to climate change. Box 25-6 details vulnerability and adaptation in rural
31 areas in Australia.

33 _____ START BOX 9-4 HERE _____

35 **Box 9-4. Drought Adaptation in Rajasthan**

37 Rajasthan in India is located in an arid ecological zone and experiences severe droughts, a condition that
38 communities have learned to cope with through conservative use of natural resources. Ways in which communities
39 have adapted to drought include ending production of crops such as wheat and cotton that require a large amount of
40 water, storing fodder for times of drought and scarcity, using savings or borrowing “from cooperatives and banks”
41 for drinking water well construction, bunding fields, digging and deepening ponds and wells to retain water,
42 growing medicinal plants to contribute to revenue, making compost using earthworms for environmentally friendly
43 fertilizer. With the help of a local NGO, women have also formed a self-help group (SHG) to collect money to lend
44 to the needy during emergencies. Additionally, a government Food-for-Work Programme helps provide
45 communities with wheat, cash, and subsidized fodder (Chatterjee *et al.*, 2005).

47 _____ END BOX 9-4 HERE _____

49 _____ START BOX 9-5 HERE _____

51 **Box 9-5. Adaptation to Extreme Events in Jamaica**

53 Extreme weather events and severe droughts have badly affected Jamaica’s households, communities, and
54 agriculture since the mid 1990’s. These changes will likely contribute to poverty and stunt Jamaica’s growth and

1 productivity. The adaptation methods that have already been used by farmers in St. Elizabeth, which is considered
2 the breadbasket of Jamaica, include planting methods such as “quick crops and the scaling down of production
3 during the dry season,” when they will mature and be ready for the market during the tourist season. This also
4 enables farmers to generate enough income to invest more during the rainy season to grow primary crops. Thus,
5 farmers try to minimize risk because they are especially vulnerable to the dry season- their success during the rainy
6 season is dependent on production during the dry season. Another adaptive strategy is to plant crops with multiple
7 uses and crops that will be more tolerant to dry spells. In southern St. Elizabeth, a dry area, successful crop
8 production depends on moisture retention, which is increase with practices such as “mulching, edging or perimeter
9 planting, drip irrigation and managing the application of water to plants”. During droughts, some farmers will
10 “sacrifice a portion of the crops under cultivation,” apply thicker mulching, borrow or share money for water, and
11 using fertilizer on leaves. To recover from drought, farmers “scale down” so that their crops are more manageable
12 and can grow successfully (Campbell *et al.*, 2011).

13
14 _____ END BOX 9-5 HERE _____

15
16 _____ START BOX 9-6 HERE _____

17 18 **Box 9-6. Adaptation Initiatives in the Beverage Crop Sector**

19
20 One of the leading initiatives to prepare small holder producers of beverage crops for adaptation to climate change is
21 the AdapCC project which worked with coffee and tea producers in Latin America and East Africa (Schepp, 2010).
22 This process used risk and opportunity analysis and participatory capacity building (CafeDirect/GTZ, 2010) to help
23 farmers identify changes in management practices to both mitigate their contribution to climate change and adapt to
24 the changes in climate they perceived to be occurring. In general the actions for adaptation were a reinforcement of
25 principles of sustainable production, such as using tree shade.

26
27 The Coffee Under Pressure project of CIAT and Green Mountain Coffee has complemented the models of changes
28 in coffee distribution with models of changes in distribution of 20 other potential crops that may have potential to
29 replace coffee where it will cease to be viable in the future. This has been complemented with detailed studies of the
30 vulnerability of producers in terms of exposition, sensitivity and capacity to adapt to climate change (Baca *et al.*,
31 2010). This indicates that there is a considerable variability in the overall vulnerability to climate change between
32 different communities in the same region and even families within the same community. Facilitating processes of
33 adaptation in this context will be a challenge, but supports the need for participatory community adaptation
34 processes that would enable families to implement strategies appropriate to their own circumstances and capacity.

35
36 Policy recommendations to support adaptation in these sectors (Eakin *et al.*, 2011; Laderach *et al.*, 2011; Schepp,
37 2010; Schroth *et al.*, 2010) have prioritized the follows interventions to support adaptation:

- 38 • Community-based analysis of climate risks and opportunities as a basis for community adaptation strategies
- 39 • Improved recording and access to climate information including medium and long-term predictions
- 40 • Sustainable production techniques including soil and water conservation, shaded production systems,
41 diversification of production systems
- 42 • Development of new varieties with broader adaptability to climate variation, higher temperatures and
43 increased drought tolerance
- 44 • Financial support to invest in adaptation and reduce risks through climate insurance
- 45 • Organization of small producers to improve access to knowledge, financial support and coordinate
46 implementation
- 47 • Environmental service payments and access to carbon markets to support sustainable practices
- 48 • Development of value chain strategies across all actors to support adaptation and increase resilience across
49 the sectors.

50
51 There are possibilities for synergy between adaptation and mitigation. The sustainability standards Rainforest
52 Alliance and Common Code for the Coffee Community are piloting climate-friendly standards for producers that
53 aim to reduce the GHG emissions from agricultural practices, increase sequestration of carbon in soils and trees, but
54 also prepare producers for adapting to climate change (SAN, 2011; Linne, 2010). The later consists of improved

1 understanding of climate impacts and promoting sustainable production practices to increase resilience in the
2 production systems.

3
4 _____ END BOX 9-6 HERE _____

7 **9.4.4. Limits and Constraints to Rural Adaptation**

8
9 The Fourth Assessment Report stated with very high confidence that there are substantial limits and barriers to
10 adaptation (Adger *et al.*, 2007). Since that time additional evidence has shown that barriers do exist to adaptation –
11 and that these barriers are both hard (physical) and soft (financial, social and cultural).

12
13 Lack of access to credit, water and land are major factors inhibiting adaptation for farmers in Africa and Asia. A
14 multinomial logit analysis of climate adaptation responses suggested that access to water, credit, extension services
15 and off-farm income and employment opportunities, tenure security, farmers' asset base and farming experience are
16 key to enhancing farmers' adaptive capacity (Gbetibouo *et al.*, 2010). A multinomial choice model fitted to data
17 from a cross-sectional survey of over 8000 farms from 11 African countries showed that better access to markets,
18 extension and credit services, technology and farm assets (labour, land and capital) are critical for helping African
19 farmers adapt to climate change. Hence education, markets, credit and information about adaptation to climate
20 change, including technological and institutional methods are important (Hassan and Nhemachena, 2008).

21
22 Rural households' lack of access to technologies and markets is also a major barrier to adaptation for certain
23 production systems. According to a study of adoption of improved, high yield maize in Zambia, production and
24 price risks could render input use unprofitable and prevent rural households from benefiting from technological
25 change crucial for adaptation (Langyintuo and Mungoma, 2008). The severe 1997 drought in the Central Plateau of
26 Burkina Faso highlighted that household with a larger resources base took the advantage of distress sales and high
27 prices of agricultural commodities (Roncoli *et al.*, 2001). A nationally representative rural household survey in
28 Mozambique from 2005 shows that, overall, using an improved technology (improved maize seeds, improved
29 granaries, tractor mechanization, and animal traction) did not have a statistically significant impact on household
30 income. However when distinguishing between households using improved technologies, especially improved maize
31 seeds and tractors, and those who do not, households who had better market access had significantly higher income
32 (Cunguara and Darnhofer, forthcoming). Social characteristics of households heads and culture both affect access to
33 adaptation options, based on modeled data from the Nile basin of Ethiopia (Deressa *et al.*, 2009) and evidence from
34 Burkina Faso (Nielsen and Reenberg, 2010), respectively.

35
36 Although access to credit, water, technologies and markets are barriers, more fundamental is access to information.
37 Since adaptation strategies involve dealing with uncertainty, whether stakeholders have access to information for
38 decision making and how they perceive and utilize this information affects their adaptation choices (Sheate *et al.*,
39 2008; Patt and Schröter, 2008; Dockerty *et al.*, 2006). Relevant information includes that on agricultural
40 technologies that can be used in adaptation, but in developing countries agricultural research and extension systems
41 are not integrated with climate planning to deliver this, as discussed by Moumouni and Idrissou (2013) for Benin.
42 There is now an important literature on dissemination of short-term or seasonal weather forecasts to farmers in
43 developing countries, as detailed in Box 9-7.

44
45 _____ START BOX 9-7 HERE _____

47 **Box 9-7. Factors Influencing Uptake and Utility of Climate Forecasts**

48
49 So far the uptake of information has been suboptimal (Vogel and O'Brien, 2006), but the potential for improved
50 prediction and effective timely dissemination has been noted in South Africa (Archer *et al.*, 2007; Klopper *et al.*,
51 2006) and also in Ethiopia (Bryan *et al.*, 2009). There have been attempts to assess factors influencing uptake and
52 utility of climate forecasts. Agent-based social simulation models show that to be effective in reducing climate risk,
53 trust in forecasts has to be high, and they have to be right 60-70% of the time to benefit smallholder farmers (Ziervogel
54 *et al.*, 2005). As well as trust, the effects of user wealth, risk aversion, and presentational parameters, such as the

1 position of forecast parameter categories, and the size of probability categories, on perceived value of seasonal
2 forecasts have been investigated (Millner and Washington, 2011). An assessment of the extent to which climate
3 change scenarios are currently used in developing adaptation strategies within the agricultural development sector in
4 Africa shows that annual climate information (such as seasonal climate forecasts) is used to a certain extent to
5 inform and support some decisions, yet climate change scenarios are rarely used at present in agricultural
6 development (Ziervogel and Zermoglio, 2009). Although, there is a large and growing literature on the role of
7 seasonal forecasts, in particular on the needs of rural end-user groups, e.g. smallholder farmers in a mountainous
8 village in southern Lesotho (Ziervogel, 2004), the optimal use of seasonal forecasts in risk management by
9 smallholder farmers is largely limited by constraints related to legitimacy, salience, access, understanding, capacity
10 to respond and data scarcity (Hansen *et al.*, 2011).

11
12 The socio-cultural context of participatory processes in the dissemination and use of seasonal forecasts is important
13 and affects who participates and what they gain (Peterson *et al.*, 2010). Rural producers in three ecological zones of
14 Burkina Faso who had taken part in appropriate participatory processes were statistically more likely to understand
15 the probabilistic aspect of the forecasts and their limitations, to use the information in making management decisions
16 and through a wider range of responses than those who had not taken part (Roncoli *et al.*, 2009). Evidence from
17 Malawi shows that forests can be important in reactive coping by providing food during shortages and a source of
18 cash for coping with weather-related crop failure – but households most reliant on forests have low income per
19 person, are located close to the forest, and are headed by individuals who are older, more risk averse, and less
20 educated than their cohorts (Fisher *et al.*, 2010). Gender differences have been observed in preferred dissemination
21 channels (Box 9-2). Debates over forecast skill and farmer skill are also common to other parts of the world such as
22 the USA, where interviews with farmers in Georgia showed that the social nature of information processing and risk
23 management bears upon the ways farmers may integrate climate predictions into their agricultural management
24 practices (Crane *et al.*, 2010).

25
26 Stakeholder networks have been used to map forecast dissemination in Lesotho, and are useful for identifying
27 obstacles (Ziervogel and Downing, 2004). There are promising signs for the integration of scientific-based seasonal
28 forecasts with indigenous knowledge systems (Ziervogel *et al.*, 2010). Ensuring improved validity and utility of
29 seasonal forecasts will require collaboration of researchers, data providers, policy developers and extension workers
30 (Coe and Stern, 2011), as well as with end users. Additional opportunities to benefit rural communities come from
31 expanding the use of seasonal forecast information for coordinating input and credit supply, food crisis management,
32 trade and agricultural insurance (Hansen *et al.*, 2011). Attempts to use longer term crop forecasting options based on
33 large-area seasonal crop yield forecasting and, genotypic adaptation based on long-term climate change projections
34 have also been examined (Challinor, 2009). Climate forecasting has also been applied to ecosystem models for use
35 in livestock farming (Boone *et al.*, 2004). The IPCC SREX report identified the use of forecasts as a risk
36 management measure (IPCC, 2012)

40

41 **9.5. Key Conclusions and Research Gaps**

42 **9.5.1. Key Conclusions**

43
44
45 There is a lack of clear definition of what constitutes rural areas, and definitions that do exist depend on definitions
46 of the urban. Across the world, the importance of peri-urban areas and new forms of rural-urban interactions are
47 increasing. Notwithstanding this, rural areas still account for almost half the world's population, about 75% of the
48 developing world's poor people and 80% of the world's hungry. Rural areas therefore are important for assessing
49 the impacts of climate change and the prospects of adaptation in these areas, constituting a dynamic, spatial
50 category. A lack of focus on the rural sector in policy making increases its vulnerability to climate change. Over
51 90% of rural people worldwide live in developing countries.

52
53 Climate change in rural areas in developing countries will take place in the context of many important economic,
54 social and land-use trends. In different regions, rural populations have peaked or will peak in the next few decades.

1 The proportion of the rural population depending on agriculture is extremely varied across regions, but declining
2 everywhere. Poverty rates in rural areas are falling more sharply than overall poverty rates, and proportions of the
3 total poor accounted for by rural people are also falling: in both cases with the exception of sub-Saharan Africa,
4 where these rates are rising. Hunger and malnutrition are prevalent among rural children in South Asia and Sub-
5 Saharan Africa, and recent hikes and volatility in priced of food exacerbated hunger and malnutrition among rural
6 households, many of which are net food buyers. In developing countries, the levels and distribution of rural policies
7 are affected in complex and interacting ways by processes of commercialisation and diversification, food policies,
8 and policies on land tenure. Rural people are subject to multiple non-climate stressors, including under-investment
9 in agriculture (though there are signs this is improving), problems with land policy, and processes of environmental
10 degradation. Stronger rural-urban linkages through migration, transfer of public and private remittances, regional
11 and international trade, inflow of investment and diffusion of knowledge (through new information and
12 communication technologies) are more positive developments. In industrialized countries, there are important shifts
13 towards multiple uses of rural areas, especially leisure uses, and new rural policies based on the collaboration of
14 multiple stakeholders, the targeting of multiple sectors and a change from subsidy-based to investment-based policy.
15

16 Cases in the literature of observed impacts on rural areas often suffer from methodological problems of attribution,
17 with regard to the difficulties of attributing extreme events to climate change, the status of local knowledge, and the
18 action of non-climate shocks and trends. However, evidence for observed impacts, both of extreme events and other
19 categories, is increasing. Impacts attributable to climate change include declining yields of major crops, some
20 extreme events such as droughts and storms, and geographically-specific impacts such as glacier melt in the Andes.
21

22 Future impacts of climate change on the rural economic base and livelihoods, land-use and regional interconnections
23 are at the latter stages of complex causal chains that flow through changing patterns of extreme events and/or effects
24 of climate change on biophysical processes in agriculture, livestock, fisheries and less-managed ecosystems. This
25 increases the uncertainty associated with any particular projected impact.
26

27 Major impacts of climate change in rural areas will be felt through impacts on water supply, food security and
28 agricultural incomes. In certain countries shifts in agricultural production, of food and non-food crops, could take
29 place. Price rises, which may be induced by climate shocks apart from other factors have a disproportionate impact
30 on the welfare of the poor in rural areas, such as female headed households and those with limited access to modern
31 agricultural inputs, infrastructure and education.
32

33 Climate change will lead to higher prices and increased volatility in agricultural markets, which might undermine
34 global food supply security while affecting rural households, depending on whether they are net-buyers or net-
35 sellers of food. The emerging literature suggests that deepening agricultural markets through trade reform and
36 institutional efforts to improve the predictability and the reliability of the world trading system as well as by
37 investing in additional supply capacity of small-scale farms in developing countries could help reduce market
38 volatility and mitigate food supply shortages which might be caused by climate change
39

40 Migration patterns will be driven by multiple factors of which climate change is only one. Given these multiple
41 drivers of migration and the complex interactions which mediate migratory decision-making by individual or
42 households, the detection of the effects of climate change on intra-rural and rural-to-urban migration remains a
43 major challenge.
44

45 Climate policies, such as encouraging cultivation of biofuels, and payments under REDD, will have significant
46 secondary impacts on land-use, and resulting negative impact on livelihoods, in some rural areas. These secondary
47 impacts, and trade-offs between mitigation and adaptation in rural areas, have implications for governance.
48

49 Valuation of climate impacts needs to draw upon both monetary and non-monetary indicators. Most studies on
50 valuation highlight that climate change impacts will be significant especially for the developing regions, due to their
51 economic dependence on agriculture and natural resources, low adaptive capacities, and geographical locations. The
52 valuation of non-marketed ecosystem services and the limitations of economic valuation models which aggregate
53 across multiple contexts pose challenges for valuing impacts in rural areas.
54

1 There are low levels of agreement on some of the key factors associated with vulnerability or resilience in rural
2 areas, including rainfed as opposed to irrigated agriculture, small-scale and family-managed farms, and integration
3 into world markets. There is greater agreement on the importance for resilience of access to land and natural
4 resources, flexible local institutions, and knowledge and information, and the association of gender inequalities with
5 vulnerability. Specific livelihood niches such as pastoralism and artisanal fisheries are vulnerable and at high risk of
6 adverse impacts, partly due to neglect, misunderstanding or inappropriate policy towards them on the part of
7 governments.

8
9 There is a growing body of literature on successful adaptation in rural areas and constraints upon it, including both
10 documentation of practical experience, and discussion of preconditions. In developing countries adaptation can be
11 linked to other development initiatives aiming for poverty reduction or improvement of rural areas, and “low
12 regrets” measures to respond to current variability can shift the trajectory from disaster-focused to longer-term
13 vulnerability reduction. Prevailing development constraints, such as low levels of educational attainment,
14 environmental degradation, and gender inequalities create additional vulnerabilities which undermine rural societies’
15 ability to cope with climate risks. The supply of information for decision-making, and the role of social capital in
16 building resilience, are key issues.

17 18 19 **9.5.2. Research Gaps**

20
21 Research on climate change in rural areas, which truly takes in their nature as areas with shifting combinations of
22 human activity, in which agriculture (food crops, non-food crops and livestock) is important but not necessarily
23 predominant, and with changing patterns of interaction with towns, is only just beginning. Such research will need
24 to be developed, and extended to rural areas and diverse categories of rural people throughout the world. One
25 relevant area will be that of improving understanding of the respective roles of climate and other factors in rural-
26 urban and rural-rural migration.

27
28 Research is required on the valuation and costing of climate change impacts which take note of the complexity and
29 specificity of rural areas, with special emphasis on non-marketed ecosystem services and specific populations that
30 have not as yet been studied. Research is also needed on the trade-offs and synergies between adaptation and
31 mitigation in rural areas, and the appropriate governance structures to enhance synergy.

32
33 More research is needed on vulnerability, to identify the most vulnerable areas, populations and social categories,
34 but it should include research on methodological questions such as conceptualizations of vulnerability, assessment
35 tools, spatial scales for analysis, and the relations between short-term support for adaptation, policy contexts and
36 development trajectories, and long-term resilience or vulnerability.

37
38 Research is needed on practical adaptation options, not only for agriculture but for non-agricultural livelihoods.
39 Adaptation research must also look at adaptations to institutions, to better enable them to address lack of access to
40 credit, markets, information, risk-sharing tools and property rights. Research into vulnerability, resilience and
41 adaptation must all improve ways to manage knowledge, both local and scientific, for adaptation.

42 43 44 **Frequently Asked Questions**

45 46 ***FAQ 9.1: Why are rural areas important in the study of climate change impacts, assessments, and vulnerability?***

47 No clear and unique definition of rural areas exist in literature, however it is clear that human settlements do not
48 only include urban areas. Nearly half of the world’s population, approximately 3.3 billion, lives in open country
49 areas. This is particularly true in developing and least developed countries, where more than 50% and 75% of the
50 population respectively lives in rural areas. These human settlements are strongly dependent on natural resources
51 and agriculture which influences their socioeconomic structures, and therefore highly sensitive to climate variations
52 – and even recent diversification is typically still natural resource-dependent (e.g. tourism, recreation). In addition,
53 these regions are usually characterized by pre-existing vulnerabilities which can aggravate climate change impacts.

1 Isolation and marginality remain as factors that significantly affect adaptive capacity in rural areas and increase
2 vulnerability.

3 There are important differences between rural areas in developing and developed countries. Rural areas in
4 developing countries are characterized by higher prevalence of poverty, isolation and lower human development. In
5 developed countries these features are also present, but they are usually associated and influenced by the proximity
6 to towns, and their role as a place for recreational activities.

7
8 **FAQ 9.2: What will be the major climate change impacts and adaptations in rural areas across the world?**

9 Given the strong dependence on natural resources, impacts of climate change in rural areas will, be primarily
10 observed as changes in the productivity of primary sectors, such as agriculture, forestry and fishing. Secondary
11 (manufacturing) industries, and the livelihoods and incomes that are based on them, will in turn be substantially
12 affected. Extreme events associated with climate change will also affect rural areas, mainly via heat stress, drought
13 and flooding that impact on infrastructure (i.e. dams, roads, buildings, telecommunications and irrigation systems).
14 Depending on the magnitude these extreme events can trigger economic and political turmoil, as well as migration.
15 Existing isolation and marginalisation create current vulnerability which, in combination with exposure to climate
16 change, increases the risks of adverse impacts.

17 Adaptation options are context-specific and will depend on the correct identification of relevant risks and the
18 adaptive capacities of rural people with differing access to natural, financial, human and social capital. Examples of
19 rural adaptations include modifying farming and fishing practices, introducing new species and varieties as well as
20 recovering old ones, diversification, water management, modifying infrastructure and technology decisions, and
21 both formal and informal risk sharing mechanisms. Adaptation will also include changes in institutional and
22 governance structures.

Table 9-1: Major findings of the IPCC Fourth Assessment Report and the International Assessment of Agricultural Science and Technology for Development.

Importance of non-climate trends	Source
The significance of climate change needs to be considered in the multi-causal context of its interactions with other non-climate sources of change and stress (e.g. water scarcity, governance structures, institutional and jurisdictional fragmentation, limited revenue streams for public sector roles, or inflexible land use patterns)	W
Different development paths may increase or decrease vulnerabilities to climate-change impacts	W
Neglect by policy-makers and under-investment in infrastructure and services has negatively affected rural areas	I
Policy neglect specifically disfavours rural women	I
Assessment of climate change impacts on agriculture has to be undertaken against a background of demographic and economic trends in rural areas	E
Global numbers of people at risk from hunger will be affected by climate change, but more by socioeconomic trends as captured in the difference between the SRES scenarios	E
Specific characteristics of smallholder agriculture	
Subsistence and smallholder livelihood systems suffer from a number of non-climate stressors, but are also characterized for having certain resilience factors (efficiencies associated with the use of family labour, livelihood diversity to spread risks)	E
Traditional knowledge on agriculture and natural resources is an important resilience factor	I, E
The combination of stressors and resilience factors gives rise to complex and locally specific impacts, resistant to modelling	E, W
Impacts on agriculture and agricultural trade	
In low-latitude regions, temperature increases of 1-2°C are likely to have negative impacts on yields of major cereals. Further arming has increasingly negative impacts in all regions	E
Increases in global mean temperatures (GMTs) of 2-3 might lead to a small rise or decline (10-15%) in food (cereals) prices, while GMT increases in the range of 5.5°C or more might result in an increase in food prices of, on average, 30%	E
Forestry	
Loss of forest resources through climate change may affect 1.1 billion poor and forest-dependent people, including through impacts on Non-Timber Forest Products.	E
Valuation	
Robust valuations of climate change impact on human settlements are rare	W
Social and environmental costs are poorly captured by monetary metrics: non-monetary valuation methods should be explored	W, I
Adaptation	
Prospects for adaptation depend on the magnitude and rate of climate change	I
Adaptation actions can be effective in achieving their specific goals, but they may have other (positive or negative) effects, including resource competition	I
Diversification of agricultural and non-agricultural livelihood strategies is an important adaptation trend, but requires institutional support and access to resources	E
Links between adaptation and mitigation	
Mitigation and adaptation policies are in many cases, and certainly for agriculture, closely linked	K, E, W

Sources: W = Wilbanks *et al.* 2007; E = Easterling *et al.* 2007; I = McIntyre *et al.* 2009; K = Klein *et al.* 2007

Table 9-2: Major demographic, poverty-related, economic, governance, and environmental trends in rural areas of developed and developing countries.

	Developed countries	Developing countries
Demographic Trends	<p>Rural population accounts for 22.3% of the total population (or about 276 million people) (UN-DESA Population Division, 2012). Rural areas account for 75% of land area in OECD countries (OECD 2006).</p> <p>Rural population has peaked (absolute numbers) in Europe and North America. Rural depopulation in some places, but also counter-urbanization with people moving from urban to rural areas elsewhere.</p>	<p>Rural population accounts for 50.3% of the total population (or about 2.5 billion people) in less developed countries (excluding LDCs), 71.5% (or about 608 million people) in the LDCs (UN-DESA Population Division, 2012)</p> <p>Rural population has already peaked in Latin America and Caribbean, East and South East Asia; expected to peak around 2025 in Middle East, North Africa, South and Central Asia; around 2045 in sub-Saharan Africa.</p>
Dependence on agriculture	<p>Agriculture accounts for only 13% of rural employment in the EU (2006), and less than 10% on average across developed countries; however, has a strong indirect influence on rural economies.</p> <p>Increased competition as a result of economic globalization has resulted in agriculture no longer being the main pillar of the rural economy in Europe. Economic policies are primary drivers. (Marsden, 1999, Lopez-i-Gelats, 2009)</p>	<p>Proportion of rural population engaged in agriculture declining in all regions(Figure 9-2).. Agriculture still provides jobs for 1.3 billion smallholders and landless workers (World Bank, 2008).</p> <p>Non-agricultural including labour-based and migration-based livelihoods increasingly existing alongside (and complementing) farm-based livelihoods. Agricultural initiatives and growth still important for adaptation and for small holders in Africa and Asia; (Osbahe <i>et al.</i>, 2008; Collier <i>et al.</i>, 2008; Kotir, 2010)</p>
Poverty and Inequality	<p>Per capita GDP in rural areas of OECD countries is only 83% of national average (but significant variation within and between countries): driven by out-migration, aging, lower educational attainment, lower productivity of labour, low levels of public services.</p>	<p>Rates of poverty (percentage of population living on less than US \$ 2/day) and extreme poverty (percentage of population living on less than US \$ 1.25/day) falling in rural areas in most parts of the world; but rural poverty and rural extreme poverty rising in sub-Saharan Africa. Recent price hikes and volatility exacerbated hunger and malnutrition among rural households many of which are net-food buyers (FAOSTATS, 2013). Hunger and malnutrition prevalent among rural children in South Asia and Sub-Saharan Africa (UN, 2010; IFAD, 2010; World Bank, 2007). Figure 9-2 and Table 9-3</p>

Table 9-2 (continued)

Economic, Policy, Governance Trends	<p>Shift from agricultural (production) to leisure (consumption) activities; focus on broader amenity values of rural landscapes for recreation, tourism, and forests, ecosystem services. (Bunce, 2008; OECD, 2006; Rounsevell <i>et al.</i>, 2007)</p> <p>Agricultural subsidies under pressure from international trade negotiations and domestic budgetary constraints. As a result of recent price hikes, domestic price support has been lowered in OECD countries.</p> <p>New policy approach in OECD countries that focuses on investments and targets a range of rural economic sectors and environmental services.</p>	<p>Interconnectedness and economic openness in rural areas have encouraged shifts to commercial agriculture, livelihoods diversification and aid knowledge transfers (section 9.3.3).</p> <p>Interlinkages between land tenure, food security and biofuel policies impact rural poverty (see Chapter 7, section 7.1 and 7.3.2 for further details)</p> <p>Decentralization of governance and emergence of rural civil society.</p> <p>Movements towards land reform in some parts of Asia (Kumar, 2010).</p> <p>Emergence of economies in transition, characterised in places by co-existence of leading and lagging regions; political and democratic decentralization expanding leading to increasing complexity of policy (World Bank, 2007).</p>
Environmental Degradation	<p>Different socio-economic scenarios have varying impacts on land use and agricultural biodiversity (Reidsma <i>et al.</i>, 2006).</p>	<p>Resource degradation, environmentally fragile lands subject to overuse and population pressures, exacerbate social and environmental challenges.</p> <p>Multiple stressors increase risk, reduce resilience and exacerbate vulnerability among rural communities from extreme events and climate change impacts (Chapter 13, Section 13.2.6) .</p>
Rural-Urban Linkages and Transformations	<p>Changes in land-use and land-cover patterns at urban-rural fringe affected by new residential development, local government planning decisions, and environmental regulations (Brown <i>et al.</i>, 2008).</p>	<p>Stronger rural-urban linkages through migration, commuting, transfer of public and private remittances, regional and international trade, inflow of investment and diffusion of knowledge (through new information and communication technologies) (IFAD, 2010). Continued out-migration to urban areas by the semi-skilled and low-skilled, reducing the size of rural workforce (IFAD, 2010). Trend for migration to small and medium-sized towns (Sall <i>et al.</i>, 2010).</p> <p>Increased volumes of agricultural trade, growing by 5% on average (annually) between 2000-2008 (WTO, 2009). New initiatives of foreign direct investment (FDI) in agriculture in the form of large-scale land acquisitions in developing countries (Anseeuw <i>et al.</i>, 2012; World Bank, 2010).</p>

Table 9-3: Poverty indicators for rural areas of developing countries.

	Incidence of poverty (%)		Incidence of rural poverty (%)		Incidence of extreme poverty (%)		Incidence of extreme rural poverty (%)		Rural people as % of those in extreme poverty	
	1988	2008	1988	2008	1988	2008	1988	2008	1988	2008
Developing World	69.1	51.2	83.2	80.9	45.1	27.0	54.0	34.2	80.5	71.6

Source: adapted from IFAD, 2010

Table 9-4: Projected changes in areas suitable for production of tropical beverage crops by 2050.

Crop	Countries	Change in climate to 2050	Change in total area by 2050	Change in distribution by 2050
Coffee	Guatemala, Costa Rica, Nicaragua, El Salvador, Honduras, Mexico	2.0-2.5°C increase in temperature 5-10% decline in total rainfall	Between 38 and 89% decline in area suitable for production	Minimum altitude suitable for production rises from 600 to 1000 m.a.s.l.
	Kenya	2.3°C increase in temperature Rainfall increase from 1405mm to 1575 mm	Substantial decline in suitability of western highlands, some decline in area optimal for production in eastern highlands	Minimum altitude for production rise from 1000 to 1400 m.a.s.l.
Tea	Kenya	2.3°C increase in temperature Rainfall increase from 1655mm to 1732 mm	Majority of western highlands loose suitability, while looses are compensated by gains at higher altitude in eastern highlands	Optimum altitude for production change from 1500-2100 m.a.s.l. to 2000-2300 m.a.s.l.
	Uganda	2.3°C increase in temperature Rainfall increase from 1334mm to 1394 mm	Considerable reduction in suitability for production across all areas	Optimal altitude change from 1450-1650 m.a.s.l. to 1550-1650 m.a.s.l.
Cocoa	Ghana, Ivory Coast	2.1°C increase in temperature No change in total rainfall	Considerable reduction in area suitable for production; almost total elimination in Ivory Coast	Optimal altitude changes from 100-250 m.a.s.l. to 450-500 m.a.s.l.

Table 9-5: Illustrative sample of studies on economic value and changes in value from climate change.

Study : Author /s	Country / Region	Findings and Estimates
Vaghefi <i>et al.</i> , 2011	Malaysia (2 degrees C rise in temperature)	Annual economic loss in rice production: \$ 54.17 million
Zhai and Zhuang, 2009	South East Asian countries : Thailand, Vietnam, Philippines	GDP reduction from loss of agricultural productivity by 2080: 1.7-2.4%
Guiteras, 2007	India	GDP reduction from agricultural losses: 1-1.8% Consumption reduction for poor: 18%
ADB and IFPRI, 2009	Asia	Annually spending for coping with adverse agricultural impacts between 2010-2050: \$4.2 - \$ 5 billion
Mendelsohn <i>et al.</i> , 2010	Mexico	Decline in farmland values for each degree of warming: 4-6000 pesos
Mendelsohn <i>et al.</i> , 2007	U.S. A. (10% average increase in temperature)	Fall in crop land values for rural communities: 13%
Mendelsohn and Reinsborough, 2007	Canada (increasing precipitation) U.S.A. (increasing temperature)	Mixed effects with some improved profits Adverse impacts on farming
Wittrock <i>et al.</i> , 2011	Canada (Canadian Global Model 2)	Crop losses under drought: CAN\$ 7-171 per hectare
Franco <i>et al.</i> , 2011	California (B1 – low emissions and A2 – medium emissions scenarios)	Annual Agricultural losses upto \$3billion Flooding increases losses
World Bank, 2010a	Mozambique (Dynamic CGE model)	Damages to agriculture, hydropower and infrastructure (including coastal areas) by 2050: \$7.6 billion
Mideksa, 2010	Ethiopia (Cline, CGCM2 and PCM)	Decline in GDP from agriculture and linked sectors: 10% from benchmark levels
Dinar <i>et al.</i> , 2008	11 African countries (Ricardian analysis; various climate scenarios)	By 2100: Total losses of \$48.2 billion to gains of \$ 90 billion In 2020 for 1.6% warmer and 3.7% dryer climate: net farm revenues decline by upto 25%
Nelson <i>et al.</i> , 2009	Africa (A2 scenario; CSIRO and NCAR models)	Food security impacts Decline in calorie consumption per capita per day by: 500 calories
Schlenker and Roberts, 2010	Africa (A1B scenario; WCRP CMIP3)	Losses for crops except Cassava: likelihood of 95% that losses exceed 7% 5% probability that losses exceed 27%
ECLAC, 2010a, b	Guatemala, Belize, Costa Rica, Honduras (SRES A2 and B2; Regional climate models)	Losses in gross value of production upto 25% (Guatemala, followed by other countries)
Seo and Mendelsohn, 2008	South America (SRES A1; Canadian Climate Centre)	Loss in incomes of farmers by: 2020: 14% 2060: 20%
Sanghi and Mendelsohn, 2008	Brazil (Climate predictions from 14 GCMs)	Annual damages between: 1 – 39%
Fallon and Betts, 2010	Southern Europe (2 degrees C rise in temperature)	Increased costs of agricultural production
Olesena <i>et al.</i> , 2011	Hungary, Serbia, Bulgaria, Romania	Negative impacts for crops in continental climatic zone

Table 9-6: Examples of adaptations in the agricultural sector in different regions.

Agricultural adaptations	Where it has been observed and source
Modifying planting, harvesting and fertilising practices for crops	Anchioreta in Brazil (Bonatti <i>et al.</i> , 2012), semi-arid mountain regions of Bolivia (PNCC, 2007), Chile (Meza and Silva, 2009), maize and wheat crops in Argentina (Magrin <i>et al.</i> , 2009; Travasso <i>et al.</i> , 2009b), South Africa and Ethiopia (Bryan <i>et al.</i> , 2009), composting and coraaling of livestock to collect waste in northern Burkino Faso (Barbier <i>et al.</i> , 2009), Sahelian region of Mali (Adepetu and Berthe, 2007), in North West Province, Limpopo Province and KwaZulu Natal, South Africa (Thomas <i>et al.</i> , 2007)
Changing amount or area of land under cultivation	Moving winter wheat northwards and expanding rice crops (Lin <i>et al.</i> , 2005), South Africa (Bryan <i>et al.</i> , 2009), expansion of fields in northern Burkino Faso (Barbier <i>et al.</i> , 2009), increase in the size of plots in the Sahelian region of Mali (Adepetu and Berthe, 2007)
Using different varieties (e.g. early maturing, drought-resistant)	Early maturing cultivars in South Brazil (Walter <i>et al.</i> , 2010), North America (Coles and Scott, 2009), drought-tolerant in Asia (Thomas, 2008; Zhao <i>et al.</i> , 2010), South Africa and Ethiopia (Bryan <i>et al.</i> , 2009), Ghana (Gyampoh <i>et al.</i> , 2008), northern Burkino Faso (Barbier <i>et al.</i> , 2009), Sahelian region of Mali and Nigeria (Adepetu and Berthe, 2007), in North West Province, Limpopo Province and KwaZulu Natal, South Africa (Thomas <i>et al.</i> , 2007)
Diversifying crops	Peruvian Andes (Lin, 2011), South America (Montenegro and Ragrab, 2010), northeastern Mexico (Eakin and Appendini, 2008; Eakin and Bojorquez-Tapia, 2008), Tasmania, Australia (Smart, 2010), in KwaZulu Natal, South Africa (Thomas <i>et al.</i> , 2007)
Commercialisation of agriculture	Income generation from natural resources (e.g. fuelwood) in the Limpopo River Basin, Botswana (Dube and Sekhela, 2007), Ghana (Gyampoh <i>et al.</i> , 2008), Limpopo Province, South Africa (Thomas <i>et al.</i> , 2007)
Water control mechanisms (including irrigation and water allocation rights)	Improved rice harvests in monsoonal Asia (Hatcho <i>et al.</i> , 2010); adaptation for quinoa (Bolivian Altiplano), tomatoes (central Brazil) and cotton (northern Argentina (Geerts and Raes, 2009); for rice in northeast China (Lin <i>et al.</i> , 2005); small water harvesting pits (known as zai) in improved yields and incomes due to improved soil moisture in Ethiopia (Amede <i>et al.</i> , 2011; Bryan <i>et al.</i> , 2009) and Burkina Faso (Hertsgaard, 2011, Barbier <i>et al.</i> , 2009), in South Africa (Bryan <i>et al.</i> , 2009), amongst rural women farmers in the Eastern Cape, South Africa (Bryan <i>et al.</i> , 2009), Ghana (Gyampoh <i>et al.</i> , 2008), dry season vegetable production through irrigation in northern Burkino Faso to enable two crop cycles (Barbier <i>et al.</i> , 2009), Sahelian region of Mali and Nigeria (Adepetu and Berthe, 2007), in Limpopo Province, South Africa (Thomas <i>et al.</i> , 2007)
Shading and wind breaks	For coffee in Brazil, Costa Rica and Colombia (Camargo, 2010), Ethiopia (Bryan <i>et al.</i> , 2009)
Conservation agriculture (e.g. soil protection, agroforestry)	Honduras, Nicaragua and Guatemala (Holt-Gimenez, 2002), Burkina Faso (Hertsgaard, 2011, Barbier <i>et al.</i> , 2009), Ethiopia (Bryan <i>et al.</i> , 2009), Sahelian region of Mali (Adepetu and Berthe, 2007)
Modifying grazing patterns for herds	Arctic (Bartsch <i>et al.</i> , 2010), East Africa (Eriksen and Lind, 2009) and southern Africa (O'Farrell <i>et al.</i> , 2009), moving livestock to less densely populated pastures in northern Burkino Faso (Barbier <i>et al.</i> , 2009) and the Sahelian region of Mali and Nigeria (Adepetu and Berthe, 2007), in North West Province, Limpopo Province and KwaZulu Natal, South Africa (Thomas <i>et al.</i> , 2007)
Providing supplemental feeding for herds/ storage of animal feed	Arctic (P. and M., 2008; Forbes and Kumpula, 2009), South Africa (Bryan <i>et al.</i> , 2009), use of sorghum and hay residue for feeding livestock in northern Burkino Faso (Barbier <i>et al.</i> , 2009), Sahelian region of Mali and Nigeria (Adepetu and Berthe, 2007), cutting fodder for livestock in Limpopo Province, South Africa (Thomas <i>et al.</i> , 2007)
Ensuring optimal herd size	Arctic (Forbes <i>et al.</i> , 2009), culling of livestock in Northern Nigeria (Adepetu and Berthe, 2007), selling of livestock northern Burkino Faso (Barbier <i>et al.</i> , 2009) and the Sahelian region of Mali and Nigeria (Adepetu and Berthe, 2007)
Developing new crop and livestock varieties (e.g. biotechnology and breeding)	Brazil and Argentina (Marshall, 2012; Urcola <i>et al.</i> , 2010), Northern Nigeria (Adepetu and Berthe, 2007)

Table 9-7: Examples of adaptations in the water sector observed in different regions.

Type	Example	Where it has been observed and source
Supply-side mechanisms	Dams	Proposed in the Volta River in Ghana (van de Giesen <i>et al.</i> , 2010).
	Reservoirs	Asia (Tyler and Fajber, 2009), particularly in areas where water stress is an issue of distribution rather than absolute shortage (Biemans <i>et al.</i> , 2011; Rivera-Ferre <i>et al.</i> 2013)
	Groundwater pumping	Arid and semi-arid South America (Burte <i>et al.</i> , 2011; Döll, 2009; Kundzewicz and Döll, 2009; Zagonari, 2010)
	Groundwater recharge	Potential identified in India (Sukhija, 2008)
	Irrigation (often using water-saving technology)	Asia (Ngoundo <i>et al.</i> , 2007; Tischbein <i>et al.</i> , 2011)
	Fog interception practices	South America (Holder, 2006; Klemm <i>et al.</i> , 2012)
	Water capture	Bolivia (PNCC, 2007)
Demand-side mechanisms	Improved management, e.g. through efficiency	Asia (Kranz <i>et al.</i> , 2010), South America (Bell <i>et al.</i> , 2011; Geerts <i>et al.</i> , 2010; Montenegro and Ragab, 2010; Van Oel <i>et al.</i> , 2010); Pampas Argentina (Quiroga and Gaggioli, 2011)
	Policies	Murray-Darling Basin Authority (MDBA) established to address over-allocation of water resources (Connell and Grafton, 2011; MDBA, 2011) See also box 26-3 on Australia's water policies;
	Reviewing allocation rights	Indogangetic Plains (Rivera-Ferre <i>et al.</i> , 2013); Australia's MDBA reviewed the "exceptional circumstances" concept in drought policy (Productivity Commission, 2009);

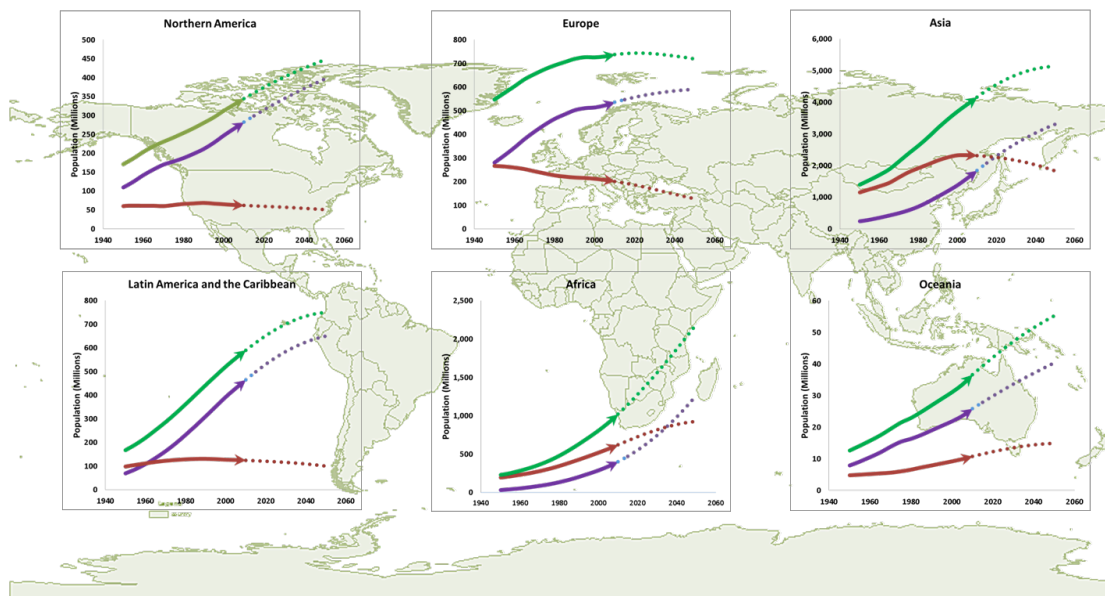

Figure 9-1: Trends in rural (red), urban (purple), and total (green) populations by region. Solid lines represent observed values and dotted lines represent projections. Source: United Nations, Department of Economic and Social Affairs/Population Division (2012).

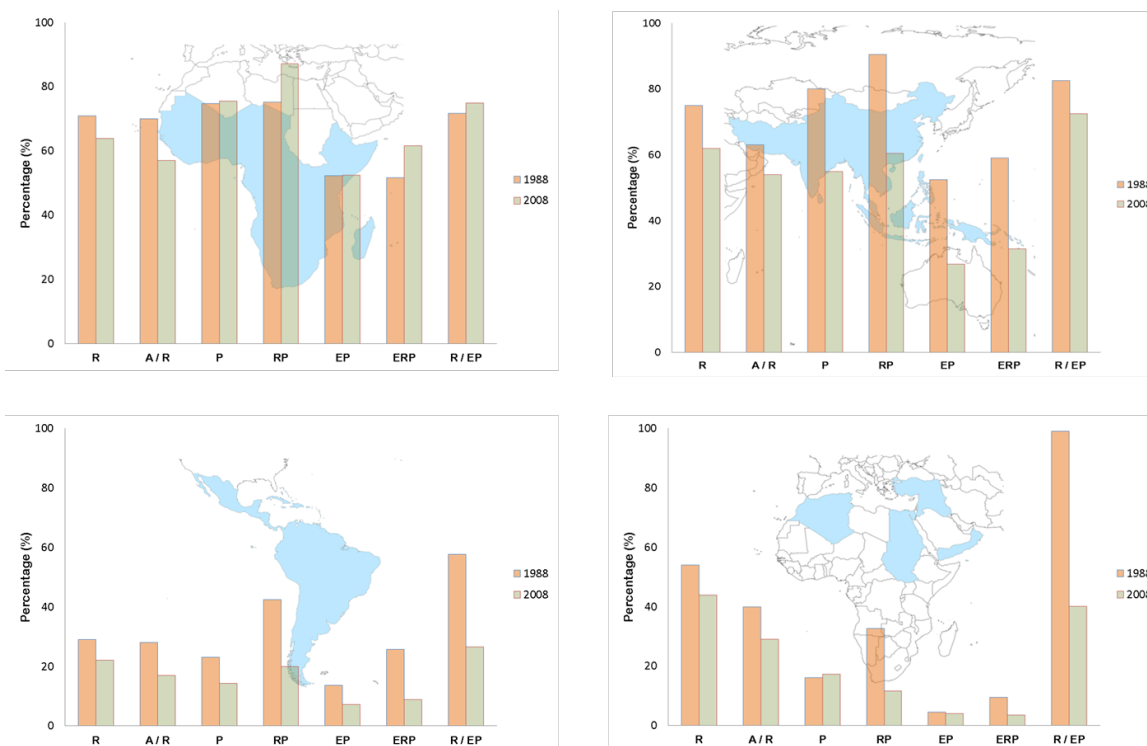

Figure 9-2: Demographic and poverty indicators for rural areas of developing countries, by region. R: percentage of rural population; A/R: agriculture as percentage of rural; P: incidence of poverty; RP: incidence of rural poverty; EP: incidence of extreme poverty; ERP: incidence of extreme rural poverty; R/EP : rural as percentage of those in extreme poverty. Source: Adapted from IFAD (2011).
